INDEX TO VOLUME CXXI.

Abbe, A. J. Partial placenta prævia in an eighteenth pregnancy, 230; a case of fracture of the spine, 433.

Abbott, G. E. The basis of rational climato-therapy, 89.

Abbott, S. L. Tetany treated successfully by urethran, 230.

Abbott, S. W. Carbonic oxide *vs.* electricity, 170.

Abdomen. A consideration of the use of gases in penetrating wounds of the abdomen, Burrell, H. L., 77; two cases of laparotomy for penetrating wounds of the abdomen, with remarks, Cabot, A. T., 81; three cases of purulent effusion in the abdominal cavity, Whittier, E. N., 467.

Abscess. Pelvic abscess in the female, Parrish, W. H., 67; cases of sub-diaphragmatic abscess, Mason, A. L., 449, 469.

Acne. Etiology and treatment of acne, 285.

Actinomycosis. A case of actinomycosis, Kneer and Conrad, 169.

Adams, J. F. A. Substitutes for opium in chronic diseases, 309, 351.

Adler, L. H. A case of cerebral syphilis following an attack of thermic fever, 255.

Air. Hot air inhalations in pulmonary tuberculosis, Trudeau, E. L., 313.

Albuminuria. Frequency of albuminuria in the sick and the aged, 516.

Alcohol. The use and abuse of narcotics and alcoholics, Child, W., 140; French International Congress for the suppression of alcoholism, report of the Senate Commission, 166; correlative progression of alcoholic lunacy and general paralytic dementia, 287.

Allen, D. P. Lithotlapaxy in children, 42.

Allen, T. H. Traumatic pelvic cellulitis, 233.

Anæmia. Relation between chlorosis, simple anæmia and pernicious anæmia, Henry, F. P., 309; the relation of anæmia to chlorosis, Forcheimer, F., 310; the urine in pernicious anæmia, 344.

Anæsthesia. Death during anæsthesia with chloroform, Mussey, J. L., 522.

Anatomy. Recent progress in anatomy, Dwight, T., 277.

Aneurism. Four cases of aneurism treated by the old method, Post, A., 576, 586.

Angina pectoris and the true cardiac neuralgias, 590.

Animals. Tumors in animals, 191

Annus medicus MDCCCLXXXIX, 640.

Antifebrin. Two cases of antifebrin poisoning, 242.

Antipyretics. Whittier, E. N., 425, 454.

Antipyrin. The subcutaneous use of antipyrin, Bach, L., 569.

Antiseptics. The use of antiseptics by country surgeons, Burns, R., 139; the use and abuse of antiseptic injections in obstetric practice, Garrigues, H. J., 434; a new antiseptic dressing, Lister, J., 522.

Aphasia. Sensory aphasia, Osler, W., 39.

Apostoli. Some clinical notes on the work of Apostoli, Hobart, M. F., 534.

Ashby, T. A. The value of laparotomy in the diagnosis and treatment of minor forms of intra-abdominal and intra-pelvic disease, 491.

Asthma. The climatic treatment of bronchial asthma, Knight, F. I., 69.

Army. Notice to candidates for appointment in the medical corps of the army, 265; fixing the status of assistant surgeons of the War of the Rebellion, 618.

Arnaudet. Endemic cancer, 73.

Arsenic. The clinical history of arsenical poisoning, Holt, A. F., 101; the anatomical appearances resulting from poisoning by arsenic, Draper, F. W., 125; the chemistry of arsenic, Hills, W. B., 152, 177; the Somerville cases of arsenical poisoning, Durell, T. M., 209; arsenic in the courts, Harris, F. A., 225.

Atkinson, E. Art of cooking, 462.

Atkinson, I. E. Some of the rarer and graver forms of cinchonism, 17.

Attendance on medical men and their families, 375.

Atwater, W. O. Food in its relation to health, 463.

Ayer, J. B. Cerebral symptoms connected with phthisis, 128, 137.

Bach, L. The subcutaneous use of antipyrin, 569.

Bacteria in milk and its products, 167.

Ball, A. B. Thrombosis of cerebral sinuses and veins, 307.

Barry. Dr. Barry's report to the Local Government Board upon an epidemic of small-pox, at Sheffield, Eng., in 1887-88, 48.

Bartow, B. The immediate disregard to malposition of the thigh in the treatment of hip disease, 411.

Beach, H. H. A. Styrone, a consideration of its value as an antiseptic, 101; cases at the Massachusetts General Hospital, 408.

Bernhardt. The treatment of tabes by suspension, 169.

Bibliography. American Orthopedic Association, transactions, Vol. I., 515; Anderson, J. W., the essentials of physical diagnosis of the chest and abdomen, 315; Ashton, W. E., questions and answers on the essentials of obstetrics, prepared especially for students of medicine, 213; Baker, W. M., and Harris, V. D., handbook of physiology, 70; Bigelow, H. R., gynecological electro-therapeutics, 541; Boston City Hospital, twenty-fifth annual report, 71; Boston City Hospital, medical and surgical reports, fourth series, 638; Buch, A. H., a manual of diseases of the ear, 213; children, cyclopædia of the diseases of children, medical and surgical, 513; Davenport, F. H., diseases of women, 165; Delafield, F., studies in pathological anatomy, 236; Gynecological Society of Boston, transactions, Vol. I., 70; Hamilton, D. J., a text-book of pathology, systematic and practical, 235; Harris, C. A., the principles and practice of dentistry, 47; Holmes, T., a treatise on surgery, 515; index catalogue, Vol. X., 345; Jacobson, W. H. A., operations of surgery, a systematic handbook for practitioners, students and hospital surgeons, 441; Keating, J. M., cyclopædia of diseases of children, Vol. II., 637; Klein, E., the bacteria in Asiatic cholera, 70; Klein, E., elements of histology, 95; Leffman, H., and Bram, W., examination of water for sanitary and technical purposes, 94; Leidy, J., an elementary treatise on human anatomy, 140; Lowell, annual report of the Board of Health, and of the city physician of the city of Lowell for the year 1888, 285; Manuel Pratique de la Garde-malade et de l' Infirmière, Tome I, Anatomie et Physiologie, 95; Manuel Pratique de la Garde-malade et de l' Infirmière, Tome V., Hygiene, 94; Martin, S., pathological report, 1887-1888, of the city of London, Hospital for Diseases of the Chest, Victoria Park, E., 93; Massachusetts Health Report, 494; Μαυρογενους, Φυσιολογικαὶ Πραγματέιαι, 141; medical news visiting list for 1889, 492; New Hampshire Eighth Registration Report, 94; Newman, D., lectures to practioners on the diseases of the kidney amenable to surgical treatment, 315; Parreidt, compend of dentistry, 94; Parvin, T., lectures on obstetric nursing, 369; Prudden, T. M., the story of the bacteria and their relations to health and disease, 515; Schnee, E., diabetes, its cause and permanent cure, from the standpoint of experience and scientific investigation, 94; Simon, W., manual of chemistry, 416; Smart, C., handbook for the hospital corps of the United States army and State military forces, 441; Swayne, J. G., obstetric aphorisms for the use of students commencing midwifery practice, 213; Young, J. K., synopsis of human anatomy, being a complete compend of anatomy, including the anatomy of the viscera and numerous tables, 118.

Billings, J. S. The United States census in its relation to sanitation, 461.

Biography. Babbitt, N. S., 500; Bartholomew, I. H., 447; Bassett, T., 596; Briggs, L. W., 424; Brown, D. T., 288; Cabell, J. L., 196; Chambers, T. K., 288; Chapman, T. L., 220; Charcot, 374; Craig, W. H., 400; Cockroft, W., 545; Cutter, D. B., 620; Day, W. DeF., 568; Elam, C., 172; Gloninger, D. S., 320; Greene, M. C., 548; Grosvenor, D. A., 348; Haddock, C., 400; Hanchett, M. E., 144; Harvey, T. B., 596; Hewson, A., 288; Hunt, M., 348; Inches, H. B., 193, 196; King, J. B., 266; Lane, M., 348; Meisberger, L., 92; Mott, A. B., 193; Nichols, C. H., 645; Otis, H. S., 148; Reed, T. L., 192; Ricord, P., 424, 447; Rush, W., 13, 20; Russell, L. B., 193, 196; Taylor, I. E., 474; Tauszky, R., 572; Thompson, A. W., 75; Ufford, E. G., 244; Upham, G. B., 169; Warner, L. F., 448.

Births. More complete registration of births, Truax, J. G., 261.

Blake, J. G. Empyema, 467.

Blindness in England, 217; some causes of preventable blindness, Derby, H., 401, 416.

Blood. The passage of portal blood with the general circulation and its probable relation to toxæmia, Stockton, C. G., 14; toxic agent in the blood as a cause of diseases of the nervous system, Crain, M. R., 65.

Boardman, W. E. Aseptic obstetrics, 45.

Boldt, H. J. Intermediate trachelorrhaphy, 490.

Booker, W. D. A study of some of the bacteria found in the dejecta of infants affected with summer diarrhœa, 415.

Boston City Hospital, twenty-fifth anniversary of, 646.

Boston Dispensary, 398.

Brackett, E. G. An experimental study of distraction of the hip, 411.

Bradford, E. H. A case of ligature of the internal jugular vein, recovery, 204, 205; removal of loose cartilages from the knee-joint, 205; president's address, American Orthopedic Association, 299.

Bradford, E. H., and Brackett, E. G. Report on progress in orthopedic surgery, 11, 35, 58.

Briggs, F. M. A case of papillomatous urethritis, 403, 416.

Briggs, W. T. The choice of operations for the removal of urinary calculi, 41.

Bright's Disease. The unicity of Bright's disease, 95, 142.

Broderick, T. J. A case of puerperal eclampsia, 157, 163.

Bronson. A rare form of skin disease, 390.

Brown, D. Psoas contraction as a symptom, 409.

Brown-Sequard. The testicle as a rejuvenator, 49.

Bulkley, L. D. What real value have the natural mineral waters in the treatment of diseases of the skin, 368.

Bull, C. S. An analysis of ninety cases of simple chronic glaucoma, with special reference to the effects of iridectomy upon the acuity of vision and the visual field, 134; contribution to the subject of

tumors of the orbit and neighboring cavities, 162; **a case of double** choked disc due to intracranial tumor, with autopsy, 162.
Bullard, W. N. Hyperostosis cranii, 188.
Bullard, W. N., and Burrell, H. L. Surgical operations for the relief of pressure paralysis in caries of the spine, 405.
Burrell, H. L. Aseptic surgery, 327; a consideration of the use of gases in penetrating wounds of the abdomen, 77, 87.
Burrell, H. L., and Cushing, H. W. Recent progress in surgery, 227, 353.
Burial. Sanitary entombment. Treat, C. R., 463.
Burns, R. The use of antiseptics by country surgeons, 139.
Busey, S. C. The effusion of chyle and of chyle-like, milky, fatty fluids into serous cavities, 308.
Bussey Bridge accident case; a review and a criticism, Page, F. W., 70.
Butlin. Pre-cancerous conditions of the tongue, 318.
Byrne, J. A digest of twenty years' experience in the treatment of cancer of the uterus by galvano-cautery, 437.
Cabot, A. T. Litholapaxy, 41; two cases of laparotomy for penetrating wounds of the abdomen, with remarks, 81, 87.
Caille, A. Membranous croup (laryngo tracheitis) in a girl twelve years of age, tracheotomy, recovery, 493; prolapsus recti due to a large stone in the bladder, 414.
Calculus. The choice of operations for the removal of urinary calculi, Briggs, W. T., 41; two renal calculi, Shattuck, F. C., 231.
Cancer. Endemic cancer, Arnaudet, 73; morphine-vaseline as a local application in cancer, 146; primary cancer of the gall-bladder and ducts, Musser, J. H., 312, 525, 553, 581; the operative treatment of cancer of the rectum, 492; recurrence of cancer of the breast after amputation, Heidenhain, 520.
Canfield, W. B. The early detection of pulmonary consumption, with microscopical demonstration of the quick method of staining the tubercle bacilli, 541.
Carpenter, J. T. Tetany and a new theory of its pathology, 307.
Carr. Salol in gastro-intestinal derangements of childhood, 421.
Casuistry in obstetrics, Parvin, T., 67.
Census. The United States census in its relations to sanitation, Billings, J. S., 461.
Chadwick, J. R. A case of nephrotomy for removal of calculus of the kidney, 491.
Chapin, H. D. The auriculo-ventricular (presystolic) sound; some considerations on cardiac disease in children, 563.
Chapman, S. H. Notes on the presence of diphtheria at high altitudes, 90.
Cheney, F. E. An uncomplicated case of progressive ophthalmoplegia externa or a symmetrical paralysis of the external ocular muscles, 224, 233.
Chervin. Slow increase of population in France, 50.
Chicago water supply and drainage district, 517.
Child, W. The use and abuse of narcotics and alcoholics, 140.
Children. Epidemic jaundice in children, Walker, J., 21; fœtal malaria transmitted by the father, 214; intestinal troubles of infancy, 215; two cases of double empyema, Huber, F., 393; subcutaneous emphysema in children, Earle, C. W., 393; membranous croup (laryngo-tracheitis) in a girl twelve years of age; tracheotomy; recovery, Caille, A., 393; the necessity of prolonged rest after some attacks of diphtheria, Earle, C. W., 394; congenital deformity of the heart, Holt, L. E., 394; tuberculosis of the testis in childhood, Koplik, H., 413; acute suppurative peritonitis following vulvo-vaginal catarrh, Huber, F., 413; sclerema neonatorum, Northup, W. P., 413; the artificial feeding of infants, Meigs, A. V., 414; a contribution to the summer diarrhœa of children, Jeffries, J. A., 414; case of diaphragmatic hernia with operation, O'Dwyer, J., 414; prolapsus recti due to a large stone in the bladder, Caille, A., 414; some practical points in the diagnosis of malaria in children, Vineberg, H. N., 415; spastic paraplegia, Latimer, T. S., 415; a study of some of the bacteria found in the dejecta of infants affected with summer diarrhœa, Booker, W. D., 415; two years' experience in the mechanical treatment of gastro-intestinal disorders in infants, Seibert, A., 416; salol in the gastro-intestinal derangements of childhood, Carr, 421; the causes and prevention of infant mortality, Walker, J., 460; the relation of the dwellings of the poor to infant mortality, White, A. C., 460; enteric fever and tubercular meningitis at the Boston Children's Hospital, Morrill, F. G., 623; stone in a child of twenty months, Richardson, M. H., 629.
Chloroform. Death during anæsthesia with chloroform, Mussey, J. L., 522; nitrite of amyl in chloroform narcosis, Powers, G. H., 595.
Chlorosis. Relation between chlorosis, simple anæmia and pernicious anæmia, Henry, F. P., 309; the relation of anæmia to chlorosis, Forcheimer, F., 310.
Chorea. Treatment of epilepsy and chorea by the correction of ocular defects, 610.
Cinchona. Some of the rarer and graver forms of cinchonism, Atkinson, I. E., 17.
Circulatory System. Chronic endocarditis, Delafield, F., 37; a case of ligature of the internal jugular vein: recovery, Bradford, E. H., 204; calcification of cardiac left ventricular wall following subacute verrucose endocarditis, Martindale, F. E., 212; the mode of action of heart tonics, 230; abstract of a remarkable case of slow pulse extending over a period of nearly two years, Prentiss, D. W., 363; thrombosis of cerebral sinuses and veins, Ball, A. B., 367; congenital deformity of the heart, Holt, L. E., 394; report on progress in thoracic disease, Shattuck, F. C., and Sears, G. G., 457; a case of aneurism in each popliteal space; ligature of each femoral artery; recovery, Michael, J. E., 540; the auriculo-ventricular (presystolic) sound; some considerations on cardiac disease in children, Chapin, H. D., 563; four cases of aneurism treated by the old method, Post, A., 576, 586; a new instrument for direct transfusion, Putnam, J. J., 588; angina pectoris and the true cardiac neuralgias, 590.
Clark, A. Sir Andrew Clark on hospitals, 96; medical success in the face of difficulties, 422.
Clarke, I. J. Ulcer of the stomach and its complications, 133.
Cleaveland, D. A. Case of poisoning by water gas, with new method of treatment; recovery, 29.
Climate. American Climatological Association, sixth annual meeting, 68; the climatic treatment of bronchial asthma, Knight, F. I., 69; the climatology of hæmoptysis in chronic lung diseases from an etiological and therapeutic standpoint, Curtin, R. G., 88; psychological factors in selecting a climate for invalids, Otis, E. O., 89; the basis of rational climato-therapy, Abbott, G. E., 89; notes on the presence of diphtheria at high altitudes, Chapman, S. H., 90; the effect of the climate of Colorado upon phthisis pulmonalis, as shown by the analysis of one hundred recorded cases, Fisk, S. A., 173.
Clothing in its relation to hygiene, Hibberd, I. Y., 460.
Club-Foot. Hysterical equino-varus, Shaffer, N. M., 280.
Coe, H. C. The treatment of laceration of the cervix by the obstetrician, 217; death from visceral affections after laparotomy, 466.
Coggin, D. Notes on some vagaries of accommodation, 162.
Cold. Subjective false sensation of cold, considered as a symptom. Mitchell, S. W., 311.
Collins, D. A. A case of puerperal eclampsia at the sixth month terminating fatally, 158, 163.
Colorado. The effect of the climate of Colorado upon phthisis pulmonalis, as shown by the analysis of one hundred recorded cases, Fisk, S. A., 173.
Conn, G. P. Disposal of garbage, 138.
Connor, P. S. Address in surgery before American Medical Association, 13; presidential address at the annual meeting of the Ohio State Medical Society, 98.
Constipation. Cumulative constipation, Field, H. M., 537.
Cook, C. H. A study of malarial fever in Eastern Massachusetts, 356, 363.
Cooking. Art of cooking, Atkinson, E., 462.
Coroners. The system of coroners in New York, 418.
Cotting, B. E. A murderer's dying confession disproved by surgical and anatomical facts, 3, 285.
Crain, M. R. Toxic agents in the blood as a cause of diseases of the nervous system, 65.
Croton. Report on the pollution of the Croton water-shed, Peters, J. C., 23.
Croup. The treatment of idiopathic croup with turpentine, 266.
Cuba. Do the sanitary interests of the United States demand the annexation of Cuba? Lee, B., 464.
Cullingworth, C. J. Position immediately following delivery, 265.
Curtin, R. G. The climatology of hæmoptysis in chronic lung diseases from an etiological and therapeutic standpoint, 88.
Cutaneous System. Etiology and treatment of acne, 286; President's address, American Dermatological Association, Graham, J. R., 293; clinical notes on herpes zoster, Greenough, F. B., 339, 549; microscopical studies of malignant tumors of the skin, Heitzmann, C., 340; the diagnosis of leprosy, especially the division of the anæsthetic form from syringo-myelia, Morrow, P. A., 342; clinical notes on syccsis capillitii, Zeisler, 389; relapse of pimphigus foliaceus after eleven years' quiescence, Sherwell, 389; a case of impetigo herpetiformis, Sherwell, 389; a rare form of skin disease, Bronson, 390; a case of urticaria pigmentosa, Stelwagon, 390; dermatological hints, Hardaway, 391; on the alleged tolerance of the iodides in syphilis, Stelwagon, 392; the occurrence of prurigo in America, Zeisler, J., 343; two cases of eczema mercuriale, Shepherd, J. F., 344; a case of lupus erythematosus, Hardaway, 366; some general suggestions in dermatological therapy, Sherwell, S., 367; what real value have the natural mineral waters in the treatment of diseases of the skin, Bulkley, L. D., 368; dermatitis papillaris, Heitzmann, L., 368; some unusual forms of dermatitis venenata, White, J. C., 583, 587.
Cutler, E. G. Some hospital cases of typhoid fever, 621, 630; impacted gall-stone, ulceration into duodenum, 630.
Dana, C. L. The treatment of locomotor ataxia by suspension, 429; effects and advantages of static electricity, 562.
Dandridge, N. P. The surgery of the spinal cord, 17.
Davenport, B. F. Report on foods, drugs and their adulterations, 155.
Davenport, F. H. Report of progress in gynecology, 111.
Debove. Coexistence of diabetes in husband and wife, 318.
Delafield, F. Chronic endocarditis, 37.
Dementia following ether, Homans, J., 2nd, 110, 114.
Dentistry. Progress in dentistry, Rollins, W. H., 130.
Derby, H. Some causes of preventable blindness, 401, 416.
Dercum, F. X. A description of two Chinese brains, 207; a note on the pli de passage inferieure interne in the human brain, 207.
Dermatitis. Some unusual forms of dermatitis venenata, White, J. C., 583, 587.
Diabetes. Coexistence of diabetes in husband and wife, Debove, 318.

Munich a healthy city, 121.
Munro, J. C. Report of twenty-four cases of acute miliary tuberculosis, 68; escharotics in the treatment of malignant disease, 204, 214.
Murderer's dying confession disproved by surgical and anatomical facts, Cotting, B. E., 3, 285.
Musser, J. H. Some clinical aspects of vomiting, 16; primary cancer of the gall-bladder and bile-ducts, 312, 525, 553, 581.
Mussey, W. L. Death during anæsthesia with chloroform, 522.
National Medical Societies. Special national medical associations, 316; the "pioneer" special national medical societies, Williams, H. W., 347; not the pioneer, Knapp, P. C., 375.
Nervous System. The surgery of the spinal cord, Dandridge, N. P., 17; concussion of the spine in its medico-legal aspect, Smith, H. H., 18; the surgery of the peripheral nerves, Richardson, M. H., 19; sensory aphasia, Osler, W., 39; Reynard's disease, Garland, G. M., 39; toxic agents in the blood as a cause of diseases of the nervous system, Crain, M. R., 65; tetanus following ovariotomy, Johnson, J. T., 67; latency of ataxic symptoms in optic atrophy, Walton, G. L., 108, 113; cerebral symptoms connected with phthisis, Ayer, J. B., 128, 137; analysis of some of the ocular symptoms observed in so-called general paresis, Oliver, C. A., 161; a case of double-choked disc due to intra-cranial tumor, with autopsy, Bull, C. S., 162; malaria as a cause of degenerative diseases of the spinal cord, Prince, M., 187; nuclear ophthalmoplegia, with poliomyelitis, Sachs, B., 188; hyperostosis cranii, Bullard, W. N., 188; spontaneous degenerative neuritis of the brachial plexus, Leszynsky, W. M., 188; interpeduncular myxosarcoma, Starr, M. A., 189; a few cases of spasm, Webber, S. G., 197; a contribution to the study of anæsthetic leprosy, with special reference to partial sensory disorders, Jacoby, G. W., 205; a description of two Chinese brains, Dercum, F. X., 207; a note on the pli de passage inferieure interne in the human brain, Dercum, F. X., 207; the pathology of sensory aphasia with an analysis of fifty cases in which Broca's centre was not diseased, Starr, M. A., 207; a later history of a case of focal epilepsy for which trephining and excision of the motor centres were performed, Lloyd, J. H., 208; multiple neuritis and infectious cerebro-spinal meningitis, Upson, H. S., 208; case of abscess of the brain, operation, death on the ninth day, Eskbridge, J. T., 209; peroneal form of progressive muscular atrophy, Sachs, B., 209; pseudo-hypertrophy, Prince, M., 209; a case of cerebral syphilis following an attack of thermic fever, Adler, L. H., 255; Friedrich's ataxia, 262; ophthalmic migraine a manifestation of hysteria, 264; frequency of certain premonitory and after symptoms in epilepsy, Hare, H. A., 265; hysterical equino-varus, Shaffer, N. M., 280; the early stage of general paralysis, Folsom, C. F., 305, 349; tetany, Stewart, J., 306; tetany, and a new theory of its pathology, Carpenter, J. T., 307; thrombosis of cerebral sinuses and veins, Ball, A. B., 307; subjective false sensation of cold considered as a symptom, Mitchell, S. W., 311; recent progress in the pathology of the nervous system, Knapp, P. C., 359, 386; surgical operations for the relief of pressure paralysis in caries of the spine, Bullard, W. N., and Burrell, H. L., 405; spastic paraplegia, Latimer, T. S., 415; wakefulness in neurasthenia, 420; the treatment of locomotor ataxia by suspension, Dana, C. L., 429; migraine, its pathology and treatment, 494; gastric epilepsy, Massolongo, 568; tetanus in Calcutta, O'Brien, 569, the bacillus of tetanus, 569; traumatic neurosis, Prince, M., 586; on methods of examination in medico-legal cases involving suits for damages for real or supposed injuries to the brain and spinal cord, Knapp, P. C., 597, 625; treatment of epilepsy and chorea by correction of ocular defects, 610; neurasthenia and dilatation of the stomach, 615; enteric fever and tubercular meningitis at the Boston Children's Hospital, Morrill, F. G., 623; congenital bilateral abducens paralysis with facial paralysis, Schapringer, A., 635; case of cervical paraplegia from dislocation, Herter, C. A., 636.
Newell, O. K. A case of stone in the bladder, 584, 587.
New Jersey. The pine belt in New Jersey: a region of sandy soil and pine forests, Platt, I. H., 90.
New York. Report on the pollution of the Croton water-shed, Peters, J. C., 23; mortality in the City of New York for 1888, 24.
Niven, J. Tuberculosis and food-supplies, 194.

O'Brien. Tetanus in Calcutta, 569.
O'Dwyer, J. Apparent physical contradiction involved in the reinflation of a collapsed lung while an opening remained in the pleural sac, 394; case of diaphramatic hernia, with operation, 414.
Oliver, C. A. An analysis of some of the ocular symptoms observed in so-called general paresis, 161.
O'Neil, W. Hair passed in the urine, 373.
Opie, T. The kinship of obstetrics and gynecology, 20.
Opium. Substitutes for opium in chronic diseases, Adams, J. F. A., 309, 351.
Orthopraxy. Report on progress in orthopedic surgery, Bradford, E. H., and Brackett, E. G., 11, 35, 58; treatment of flat-foot, Whitman, R., 86; a case in which the night-cries of hip-disease were stopped by fixing the leg, Goldthwait, J. E., 280; cicatricial contraction of fingers, Phelps, A. M., 280; hysterical equino-varus, Shaffer, N. M., 280; the management of hip joint disease from an anatomical basis, Phelps, A. M., 281; president's address, American Orthopedic Association, 299; psoas abscess following Pott's disease, Gibney, V. P., 313; knock-knee, club-foot, deformity following hip-disease, Wyeth, J. A., 314; ultimate results of osteotomy and osteoclasis, Goldthwaite, J. E., 336; the typhoid spine Gibney, V. P., 409; the relation of the thoracic and abdominal walls to the spinal column considered with respect to the treatment of antero-posterior curvature, Weigel, L. A., 409; psoas contraction as a symptom, Brown, D., 409; the prevention of the short leg of hip-disease, Judson, A. B., 410; a case of caries of the ankle treated conservatively, Foster, C. C., 410; report of cases of caries of the ankle treated by excision, Scudder, C. L., 410; rest and fixation in hip-disease, Willard, DeF., 410; abscesses in hip-disease, their prevention, significance and treatment, Lovett, R. W., and Goldthwait, J. E., 410; the treatment of hip-disease, 411; congenital

dislocation at the hip, Ridlon, J., 411; the immediate disregard to malposition of the thigh in the treatment of hip-disease, Bartow, B., 411; an experimental study of distraction of the hip, Brackett, E. G., 411; an analysis of twenty-one cases of hip-disease treated by the Thomas splint, Huddleston, J. H., 411; fixation and traction in the treatment of hip-joint disease, Ridlon, J., 412; excision of the hip-joint, Sayre, R. H., 412; when shall treatment be dispensed with in spondylitis, Ryan, G. W., 412; acute arthritis of infants, Townsend, W. R., 413; the abscesses of hip-disease, their prevention and treatment, Lovett, R. W., and Goldthwait, J. E., 503; spastic torticollis apparently due to faulty position of the eyes, and cured by tenotomy, Wadsworth, O. F., 505.

Osler, W. Sensory aphasia, 39; notes on intra-thoracic growths developing from the thyroid gland, 290.

Otis, E. O. Psychological factors in selecting a climate for invalids, 89.

Otitis. Three deaths following otitis, with two autopsies, Wilson, F. M., 115.

Ovariotomy. Tetanus following ovariotomy, Johnson, J. T., 67; a case of ovariotomy complicated with pregnancy, Richardson, M. H., 480.

Oxygen. The therapeutic value of oxygen inhalation, with exhibition of animals under high pressure of oxygen, Thompson, W. G., 91.

Page, F. W. A Bussey Bridge accident case, a review and a criticism, 70.

Pain in the small of the back and thighs, Jeffries, J. A., 332.

Pancreas. A case of hæmorrhagic pancreatitis, Thayer, W. S., 506; cases of pancreatic hæmorrhage, Harris, F. A., 606, 608; acute inflammation of the pancreas, its symptoms and results, Fitz, R. H., 607.

Parasites. The new tænicides, 371.

Paris Letters, 73, 122, 218, 242, 374, 446, 570.

Parr, R. Action of quinine on the pregnant uterus, 193.

Parker, W. T. The over-crowding of our homes, 460.

Parrish, W. H. Pelvic abscess in the female, 67.

Parsnip. Cases of wild-parsnip poisoning, Phillips, G. A., 22.

Parvin, T. Casuistry in obstetrics, 67.

Pepper, W. Address on general medicine before American Medical Association, 13.

Peritonitis. Chronic peritonitis, with special reference to the differential diagnosis of some of its varieties, Jacobi, A., 437.

Perkins, G. W. External urethrotomy for traumatic stricture complicated with extensive false passage, 62.

Perkins Institution for the Blind, 398.

Peters, J. C. Report on the pollution of the Croton water-shed, 23.

Pfeiffer, O. G. An interesting case of tracheotomy, 185.

Pharmacopœia of 1890, Prentiss, D. W., 39.

Phelps, A. M. Cicatricial contraction of fingers, 280; the management of hip-joint disease from an anatomical basis, 281.

Phenacetin in pertussis, Irwin, G. C., 241.

Phillips, G. A. Cases of wild-parsnip poisoning, 22.

Phthisis. Four cases of phthisis treated by inhalations of hot air, Sears G. G., 33; food in the treatment of pulmonary consumption, Solis-Cohen, S., 66; the use of hot air in phthisis, Jeffries, J. A., 121; cerebral symptoms connected with phthisis, Ayer, J. B., 128, 137; phthisis among the Sioux Indians, Treon, 169; the effect of the climate of Colorado upon phthisis pulmonalis, as shown by the analysis of one hundred recorded cases, Fisk, S. A., 1,3; the influence of microbicide medicines in the treatment of phthisis pulmonalis, 190; the disposal of the sputa in phthisis, 442; open-air treatment of phthisis, Farnham, E., 595.

Physician. The fashionable consulting physician, 195.

Physical Culture, 566.

Physiology. Address before American Medical Association, Shattuck, F. C., 1; the passage of portal blood into the general circulation and its probable relation to toxæmia, Stockton, C. G., 14.

Pine Belt of New Jersey, a region of sandy soil and pine forests, Platt, I. H., 90.

Placenta Prævia. A case of partial placenta prævia in a multipara, Sinclair, A. D., 157; partial placenta prævia in an eighteenth pregnancy, Abbé, A. J., 230

Platt, I. H. The pine belt of New Jersey, a region of sandy soil and pine forests, 90.

Pneumonia. A new plan for the treatment of pneumonia, Martine, G. R., 15; double typhoid pneumonia, followed by empyema, Donovan, J. A., 23; a remarkable epidemic of pneumonia, 121; pneumonia, its mortality and therapeutics, Porter, W. B., 139; the treatment of acute lobar pneumonia, Truax, J. G., 234; treatment of pneumonia, 359; an unusual case of pneumonia, Porter, W., Jr., 628.

Poisons. Cases of wild-parsnip poisoning, Phillips, G. A., 22; case of poisoning by water-gas, with new method of treatment, recovery, Cleveland, D. A., 29; the clinical history of arsenical poisoning, Holt, A. F., 101; the anatomical appearances resulting from poisoning by arsenic, Draper, F. W., 125; the venom of snakes, Waddell, L. A., 147; a fatal case of tobacco poisoning by tobacco smoke, Richardson, B. W., 194; the Somerville cases of arsenical poisoning, Dureil, T. M., 200; two cases of antifebrin poisoning, 242; tyrotoxicon poisoning, Martin, J. N., 512.

Polk, W. M. The surgical treatment of posterior displacements of the uterus, 489.

Population. Slow increase of population in France, Chervin, 50.

Porter, C. B. Extroversion of the bladder, 40.

Porter, W. B. Pneumonia, its mortality and therapeutics, 139.

Porter, W., Jr. An unusual case of pneumonia, 628.

Post, A. Four cases of aneurism treated by the old method, 576, 586; some considerations concerning syphilis and marriage, 600, 608.

Potter, W. W. Boracic acid in gynecic practice, 21.

Pott's Disease. Psoas abscess following Pott's disease, Gibney, V. P., 313.

Powers, G. H. Nitrite of amyl in chloroform narcosis, 595.

Practice of Medicine. Address before American Medical Association, Shattuck, F. C., 1; New York physicians must be able to read and write, 289.

Pregnancy, Affections connected with. A series of five hundred cases of confinement in a maternity, Price, J., 20; the application of the forceps to transverse and oblique portions of the head, description of a new forceps, 20; the kinship of obstetrics and gynecology, Opie, T., 20; the pathology of ecto-pic pregnancy and pelvic hæmatocele, Wathen, W. H., 21; the report of a case of ectopic gestation successfully treated by galvanism, Taylor, W. H., 21; pregnancy and operative surgery, their mutual relations, Gordon, S. C., 22; the induction of premature labor in Bright's disease, Tyson, J., 39; the third stage of labor, Swift, J. B., 44; aseptic obstetrics, Boardman, W. E., 45; a case of partial placenta prævia in a multipara, Sinclair, A. D., 157; a case of puerperal eclampsia, Broderick, T. J., 157, 163; a case of puerperal eclampsia at the sixth month, terminating fatally, Collins, D. A., 158, 163; casuistry in obstetrics, Parvin, T., 67; a case of hydrencephalocele, Marion, H. E., 159; tubal pregnancy, operation, recovery, Haven, G., 160; action of quinine on the pregnant uterus; Park, R., 193; labor at full term, undilatable condition of the cervix due to cicatricial tissue, spontaneous rupture of the uterus, Lusk, W. T., 210; an extra-uterine pregnancy dating thirty-three years, Tarnier, 216; Chinese obstetric customs and superstitions, Fielde, A. M., 216; the treatment of laceration of the cervix by the obstetrician, Coe, H. C., 217; partial placenta prævia in an eighteenth pregnancy, Abbé, A. J., 230; the diagnosis and the treatment of ectopic pregnancy, Hanks, H. T., 241; position immediately following delivery, Cullingworth, C. J., 265; interesting cases observed in the New England Hospital for Women and Children during the years 1888 and 1889, Hurd, K. C., 283; posture after confinement, Zakrzewska, M. E., 319; a case of delivery of the breech by the forceps, Townsend, C. W., 432, 441; pregnancy and operative surgery, their mutual relations, Gordon, S. C., 3-5; the use and abuse of antiseptic injections in obstetric practice, Garrigues, H. J., 434; treatment of post-partum hæmorrhage by curetting the uterus, 443; a case of ovariotomy complicated with pregnancy, Richardson, M. H., 480, 486; the relation of uterine retro-deviation to pregnancy, Martin, A., 489; partial rotation of the ovum in early pregnancy as a cause of placenta prævia, Sawyer, E. W., 491; the protective influence of vaccination during the intra-uterine existence of the fœtus, Kolloch, C., 491; breech presentation, successful delivery with forceps, King, N., 512; report of one hundred and eighty-seven cases of midwifery in private practice, Zakrzewska, M. E., 557; five hundred and nine cases of labor, Townsend, C. W., 603, 610; a case of reduced labor on account of albuminuria, Stedman, C. E., 6-9.

Prentiss, D. W. The pharmacopœia of 1890, 39; abstract of a remarkable case of slow pulse extending over a period of nearly two years, 303.

Preston, G. J. A review of hypnotism, 541.

Price, J. A series of five hundred cases of confinement in a maternity, 20.

Prince, M. Malaria as a cause of degenerative disease of the spinal cord, 87; psuedo-hypertrophy, 209; traumatic neurosis, 586.

Pulse. Abstract of a remarkable case of slow pulse, extending over a period of nearly two years, Prentiss, D. W., 303.

Putnam, J. J. A supplementary inquiry into the frequency with which albumin is found in the urine, 312, 330; a new instrument for direct transfusion, 588.

Quack Medicine in Germany, Stephenson, F. B., 290.

Quinine. Action of quinine on the pregnant uterus, Park, R., 193.

Rachitis considered in relation to some of its special symptoms, Lee, W., 540.

Randall, B. A. Inflammation of the tympanic attic and perforation of Shrapnell's membrane, 114.

Recent Progress. Orthopedic surgery, Bradford, E. H., and Brackett, E. G., 11, 35, 58; gynecology, Davenport, F. H., 111; dentistry, Rollins, W. H., 130; foods, drugs, and their adulterations, Davenport, B. F., 155; ophthalmology, Standish, M., 181; Surgery, Burrell, H. L., and Cushing, H. W., 227, 253; anatomy, Dwight, T., 277; nervous system, Knapp, P. C., 359, 386; thoracic disease, Shattuck, F. C., and Sears, G. G., 457; therapeutics, Williams, F. H., 481, 508.

Registration. Maine registration law decided not to be a law, 50; more complete registration of births, Truax, J. G., 261.

Respiratory System. A new plan for the treatment of pneumonia, Martine, G. R., 15; double typhoid pneumonia followed by empyema, Donovan, J. A., 23; four cases of phthisis treated by inhalations of hot air, Sears, G. G., 33; report of twenty-four cases of acute milliary tuberculosis, Munro, J. C., 68; the climatic treatment of bronchial asthma, Knight, F. I., 69; the pathology of hæmoptysis from chronic pulmonary disease, Garland, G. M., 69; the climatology of hæmoptysis in chronic lung diseases, from an etiological and therapeutic standpoint, Curtin, R. G., 88; a remarkable epidemic of pneumonia, 121; the use of hot air in phthisis, Jeffries, J. A., 121; cerebral symptoms connected with phthisis, Ayer, J. B., 128, 137; pneumonia, its mortality and therapeutics, Porter, W. B., 139; drainage in gangrene of the lung, Malagodi, 146; phthisis among the Sioux Indians, Treon, 169; the effect of the climate of Colorado upon phthisis pulmonalis, as shown by the analysis of one hundred recorded cases, Fisk, S. A., 173; an interesting case of tracheotomy, Pfeiffer, O. G., 185; the influence of microbicide medicines in the treatment of phthisis pulmonalis, 190; the treatment of acute lobar pneumonia, Truax, J. G., 234; hot air inhalations in pulmonary tuberculosis, Trudeau, E. L., 313; treatment of pneumonia, 359; two cases of double empyema, Huber, F., 393; sub cutaneous emphysema in children, Earle, C. W., 393; membranous croup (laryngo tracheitis) in a girl twelve years of age, tracheotomy, recovery, Cailie, A., 393; apparent physical contradiction involved in the reinflation of a collapsed lung while an opening remained in the pleural sac, O'Dwyer, J., 394; the disposal of the sputa in phthisis, 442; the rehabilitation of the spittoon, 442; report on progress in thoracic disease, Shattuck, F. C., and Sears, G. G., 457; empyema, Blake, J. G., 467; pyo-pneumo-thorax, Mason, A. L., 467; nasal stenosis, Langmaid, S. W., 513; ice in the night sweats of phthisis Rosenbach, 520; papilloma of the vocal cord, Knight, F. I., 538; the early detection of pulmonary consumption, with microscopical demonstration of the quick method of staining tubercle bacilli, Canfield, W. Address.

OPENING ADDRESS TO THE SECTION OF PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.[1]

BY FREDERICK C. SHATTUCK, M.D., CHAIRMAN OF THE SECTION.

In obedience to the rule of the association that the chairman of each section shall review the progress which the year has brought in those subjects which immediately concern his section, I ask your attention to a very brief consideration of a few of the large number of topics which might worthily find notice here. The practice of medicine, materia medica, and physiology include so much, the workers are so many, and the fruits of their labors are so varied and abundant that the difficulty of selection is itself an embarrassment.

The grass had scarcely grown on the grave of the treatment of pulmonary tuberculosis by gaseous enemata before another curative method was advocated by Weigert,[2] Halter,[3] and Krull,[4] a method which would seem at first sight to have claims to be called curative in that it is designed to remove the cause of the disease by destroying the bacilli *in situ*. We know that the development of this particular microbe is arrested at a temperature of 107° F.; and if, then, the intra-pulmonary temperature can be raised to or above this point and there maintained for a time, the happiest results must follow. I can confirm the statements of the originators of this method as to the ability of patients to breathe with impunity air at a surprisingly high temperature. I have myself inhaled it at 320° F., and seen patients inhale it at 428° F. without notable inconvenience. Nearly six months ago Dr. G. G. Sears, of Boston, began to practise inhalations of hot air on some of my patients in the House of the Good Samaritan. His results are now ready for publication, and it will suffice to say here that an apparatus was used devised by Mr. G. L. Kingsley, of the Harvard Medical School, an apparatus which can be made by any copper-smith for $5, — that patented by Weigert costs in this country $75, — and that we are satisfied that the problem of intra-pulmonary direct germicidal action is still unsolved.

The pancreas, an organ the diseases of which have been until recently of pathological rather than clinical interest, is being dragged from obscurity. Senn's work on cysts of the pancreas is followed up by Fitz,[5] who has collected seventy cases of the several forms of acute inflammation of the organ and subjected them to a rigid analysis which yields a notable increase to our knowledge. A frequent cause of acute pancreatitis seems to be the extension of an inflammation from the duodenum into the pancreatic duct and thence to the interstitial tissue of the organ; which tissue stands in such relation to the peritoneum, the retroperitoneal and retropancreatic fat tissues, as to permit the ready passage of bacteria, and thus account for the peritonitis and disseminated fat-necrosis so often resulting from pancreatic inflammation. Inflammation of this organ is doubtless much more common than has hithero been generally supposed, and is not impossible of diagnosis. The affections with which it is most likely to be confounded are irritant poisoning, perforating gastric or duodenal ulcer, perforation from gall-stones, and acute intestinal obstruction. The first three can be excluded by the history of the case and the associated symptoms; the last by determining the patency of the large intestine through injection, by the seat of the pain and tenderness in the upper abdomen, and by the absence of marked tympanites. I trust that I may be pardoned here for bringing in my own personal experience, which I do with the less hesitation inasmuch as it is not especially to my credit. It was my lot during the past winter to be one of six physicians and surgeons at a consultation: four of us considered the case as probably acute intestinal obstruction, one inclined to perforation, while Dr. Fitz alone held that it was acute pancreatitis and advised against operation. Laparotomy was done, no obstruction was found, multiple fat-necrosis was seen in the omentum, and the autopsy revealed acute hæmorrhagic pancreatitis.

Frerichs long ago noticed the frequency of atrophy of the pancreas in diabetes mellitus; and Lancereaux,[6] in a recent and important paper, calls attention to the relation between these conditions, based on twenty cases which he has seen, with post-mortem verification in fourteen of these. Pancreatic diabetes, in contradistinction from the other forms of the affection, is characterized by sudden onset, rapid course, and severity of the symptoms with great emaciation. In two of the cases, by the way, epigastric colic led to the diagnosis of pancreatic calculus, and the autopsies brought justification.

Here we may allude to the experiments of Pavloff and Smirnoff,[7] which show that in rabbits whose pancreatic ducts have been ligated regeneration of the gland may take place after a new and spontaneous communication with the intestine has been formed.

The much-vexed question as to the nature of diabetic coma, with the indications for the liability of its occurrence in any particular case and the means for its relief, are ably considered by Kirstein,[8] who details the steps through which our present knowledge has been attained. In certain cases of diabetes the organism seems to have lost the power of burning the fatty acids, largely oxybutyric acid, to their normal end products. These cases are characterized by a large increase in the amount of ammonia in the urine rather than by any striking symptoms or complex of symptoms, and these are the cases in which coma is to be dreaded; this form of coma being the result of the formation of larger amounts of free acid than can be neutralized by the ammonia which the organism is capable of supplying, the consequent abstraction from the blood of the fixed alkalies, and thus toxæmia. The quantitive estimation of ammonia in the urine of diabetics is consequently of great importance therapeutically, as well as for prognosis; but, unfortunately, a method for this estimation, readily applicable to clinical purposes, is still lacking. When this

[8] Deutsch. Med. Wochenschrift, April 11, 1889.

large excess of ammonia is found the indications are to restrict the acid rather than the sugar-forming foods, — meats, for instance, — and to give alkalies freely. On the advent of the peculiar dyspnœa, which is apt to be the first symptom of coma, alkaline intravenous injection is to be practised, as has already been done in a small number of cases, Minkowski alone having saved his patient.

The diseases of the blood have been studied by Graeber, Hunter, and others. According to Graeber,[9] anæmia, chlorosis, and pernicious anæmia are distinguishable from one another by a count of the red corpuscles and an hæmoglobin estimation. Hunter[10] argues to show that pernicious anæmia is an entity, pathological and clinical; depends on increased blood destruction, probably in the liver; and is to be differentiated from all secondary grave anæmias, as, for instance, those of cancer and intestinal parasites, as well as from all other primary anæmias, by the greatly increased amount of blood pigment, responding to the micro-chemical tests for iron, found in the liver in this affection. The spleen contains no such excess of iron as does the liver, and in the latter organ the seat of the pigment is chiefly the outer portions and cells of the lobules, not the capillaries, a fact which goes to show that the blood destruction takes place in the liver itself, the pigment entering the cells in soluble form — hæmoglobin — and there undergoing conversion into albuminate of iron. In all cases where the blood destruction takes place elsewhere than in the liver, and pigment is deposited in that organ, it accumulates in and about the capillaries.

A paper of MacMunn,[11] of Wolverhampton, on Addison's disease is noteworthy. He has studied the adrenals and urine of patients with this disease spectroscopically; and, reviewing our knowledge of the subject, concludes that the function of the adrenal bodies is the removal from the circulation of worn-out pigments and their accompanying proteids. "When the adrenals are diseased, these effete pigments and effete proteids circulate in the blood; the former, or their incomplete metabolites, producing pigmentation of the skin and mucous membrane, and appearing often in the urine as urohæmatoporphyrin; the latter producing toxic effects, and leading to further deterioration of the blood with its consequences."

During the past year the internal antipyretics have continued to seek their level. It is seen that they exert no curative influence on specific febrile processes; and, as we recognize more and more clearly that even continued fever is not productive of the changes in the parenchymatous organs with which we credited it of late years, but that the danger in these processes lies rather in the effects of toxic alkaloids on the nervous centres than in temperature elevation,—as we recognize this fact we appreciate how irrational it is to address our therapeusis chiefly to pyrexia. When the fever is in itself productive of discomfort to the patient the internal antipyretics are useful; but the indications seem to me, at least, strong that the antineuralgic and analgesic will survive the antipyretic application of this class of drugs. On the other hand, it seems probable that the cold bath treatment of continued, and especially of typhoid, fever must be adopted and conscientiously carried out in this country. As the principles of Brand's method gain headway in France, a country not prejudiced in favor of German leadership; as Brand's results are confirmed by other observers and in other countries; and in the face of such statistics as are put into our language by H. C. Wood,[12] Wilson,[13] and Baruch,[14] — it is difficult to see how a people which prides itself on its wealth, general intelligence, and practical qualities can be longer deterred by scepticism, or motives of convenience and economy, from the adoption of a method of treatment which reduces the mortality of typhoid fever to 3%.

The hypnotics sulphonal and amylene hydrate have come into more general use, and prove themselves to be valuable additions to our list of remedies of this class. Unpleasant effects seem rare, while the slow absorption of the one and the rapid action of the other gives each a place.

The treatment of locomotor ataxia by suspension (accidentally hit upon by Motchonkowsky of Odessa, who was struck by the benefit derived by a tabetic patient, also suffering from spinal curvature, after the suspension required in applying a plaster jacket) has spread with great rapidity, and is being thoroughly tested in this as well as in other countries. It is still too early to determine how useful it will prove to an unfortunate class of patients.

At our meeting in Cincinnati last year a discussion took place on the modern methods of diagnosis in diseases of the stomach, and high hopes were expressed that by the examination of the gastric contents an ease and certainty of diagnosis in these affections is almost within our reach, comparable to that which urinary analysis yields in renal disease. The more carefully the question is studied the greater is the demand for yet further study, and the more clearly does the necessity appear for the exercise of great caution in the formation of definite conclusions at present. In the first place, it is now seen that the only single test for hydrochloric acid which has a real clinical value is the phloroglucin-vanillin; the tropæolin, congo red, methyl violet, and other tests either reacting to other acids or acid salts, or being often prevented from reacting by albuminoids, even when free hydrochloric acid is present. Secondly, it gradually appears that it is not safe to base a diagnosis of gastric cancer on even the persistent absence of this acid from the gastric contents withdrawn an hour after a test meal. Such absence is indicative of notable impairment of the functional activity of the mucous membrane, as from a severe catarrhal condition; or of extensive destruction of the secretory glands of the stomach, largely irrespective of the cause of the destruction. Thus, in a case of cancer sharply localized and unaccompanied by catarrh to any marked degree, free hydrochloric acid may be found in sufficient amount until the cachexia is well advanced. On the other hand, in severe but simple catarrh, especially if attended by the formation of much mucus; in atrophy of the gastric tubules; in amyloid disease of the organ; after strong caustics have done their work; even

in certain cases of impaired innervation,— no free hydrochloric acid may be detected, though sought for repeatedly with the utmost skill and the aid of every appliance and reagent.

It also appears that hyperacidity, though a frequent, is by no means a constant, accompaniment of peptic ulcer.

Indeed, it is impressed upon us that the pathology of an organ which varies so widely physiologically in the same individual within such short periods of time is a very complicated thing; and the lesson is again enforced that it is not in pathognomic signs, but in careful weighing of each piece of evidence and in the painstaking collocation of them all, that accurate diagnosis is to be attained.

Before leaving this subject I must say a word in praise of Ewald's remarkable work on diseases of the stomach,[15] and of the balance which he preserves while enthusiastically pursuing his subject.

Morton Prince[16] was led by his duties as examiner of applicants for the Boston Fire Department, and by the frequency with which he heard temporary murmurs in vigorous men, to a study of their mode of origin. It has been believed for some years that in debilitated states leakage may take place through the mitral valve, the curtains of which are not tightly closed by reason of the insufficient force of the ventricular contraction. It will be at once appreciated that Prince's cases were the reverse of debilitated; and his ingenious explanation of the murmurs heard in them is that under conditions of great excitement, such as many of the applicants presented, the valve may be forced by ventricular contractions of a power disproportioned to the resistance of the valve. It is not easy to detect a flaw in his argument, and it seems as if he had made an important addition to our knowledge.

There are many other subjects of which I should like to speak did time permit, and were the programme less attractive. Very likely another in my place would have selected quite a different series of topics. The highly important and interesting subject of cerebral localization, for instance, has not been mentioned. But the work which has been done in that direction the past year has been rather in popularizing previous studies, and in the application of their results to practical surgery, than in new discovery.

Prudden's[17] studies of diphtheria and the constancy with which he finds a streptococcus in diphtheritic lesions deserve more than passing mention. So also Hare's Fothergillian prize essay on mediastinal disease.

To sum up the results of the year, it may be stated that it has been one of real though not of brilliant progress. Knowledge has been advanced almost all along the line, more in some parts than in others; bacteriology in its broad sense, including the chemical poisons generated by or accompanying the microbes as well as the identification and life-history of the organisms, offering an enormous field for patient research. One fact seems to me to stand out in strong relief; namely, that our countrymen are on the high-road leading to the attainment of a reputation for scientific research equal to that which they have long enjoyed in the more immediately practical branches of medicine and surgery.

The future glows with a promise which the achievements of the past assure us will be realized; and it is the part of each one of us, if he cannot discover, at least to do all that in him lies to make the highest and best use of the discoveries of others more gifted than himself.

A MURDERER'S DYING CONFESSION DISPROVED

BY SURGICAL AND ANATOMICAL FACTS;

Read before the Massachusetts Medico-Legal Society, June 11th, 1889.

BY BENJAMIN E. COTTING, M.D., &c.,

Senior Consulting Surgeon to the Boston City Hospital, Associate member of the Society.

ON the afternoon of July 1st, 1874, a woman, twenty-two years of age, of no very uncertain character, was brought to the Boston City Hospital. She was completely paralyzed on the right side; seemed nearly or wholly unconscious; and had fearful and bloody injuries about the head. The story that came with her was that she had been found in this condition, a few hours before, in her "own hired" room, and in her own bed. When found she was motionless, and was at first supposed to be without life. Her head, neck, and shoulders were red with blood; and under them the pillows, sheets, and bedding were saturated with it. This blood had flowed freely from a number of open wounds on the left side of the head; but there was no spattering on the walls or objects near by. She was lying on her right side, with face towards the middle of the room, in the exact position apparently that she had taken on first going to sleep. Her night-gown and the bed-clothing about her body had not been perceptibly disturbed. Her day garments and smaller articles were orderly distributed about the room, as left on retiring. There was no sign discoverable that indicated the presence of any other person during the night. The room-door was locked, and the key remained in the lock on the inside. The windows were closed, but one was found unbolted. Through this a person could have entered, or escaped, as the room was on the ground floor; yet a most diligent search failed to reveal even the slightest evidence that anything of the kind had been done. At what hour she retired no one could tell; and no response had been gained to repeated applications to her door in the course of the forenoon. Although an adjoining room on the same floor had been occupied that night, its inmates declared that they had not heard a groan or a sound from her apartment.

So far as known she had not an enemy; yet doubtless had angered some one, inasmuch as an unrecognized man had asked for her the evening before, and, not finding her at home, had vowed terrible vengeance as he left the house.

Who did the deed, and what the instrument, were mysteries that seemed at the time to be past finding out.

On examination at the hospital several extensive and complicated fractures of the skull were discovered, with considerable depressions, thought to be chiefly in the outer tablet and not requiring trepanning. On and through the scalp were a number of bleeding wounds, — the hospital record says "nine on the left side of the head, besides several others near the left ear which cannot be separated." The ear itself was "greatly lacerated," caught as it must have been several times on the edge of the instrument when it passed into the scalp. Its helix also, with the cartilage, was cut through at its anterior upper part. These wounds were all of a curved or crescent shape, clean cut, each "little more than an inch long." From two of them "brain substance protruded in a mangled state;" and into one of them, the only one mangled, the finger could be passed, and carried through the broken skull to a considerable depth, without force, in the injured brain — the record states "fully two inches," and Dr. Cowles markedly (on his finger) confirms this statement. The lines of these wounds turned generally in one direction, inclining towards each other at various small angles; in several instances running together or crossing; some mingling in a confused or inseparable manner — particularly at the spot where the finger could be passed into the brain. The little points or tongues of skin, wherever these wounds crossed each other, were perfect to their very tips, and showed no sign whatever of rent or bruise.

The hair was very long and very thick: "We noticed it," Dr. Cowles writes, "to have been cut off quite sharply in correspondence with the cuts in the skin. . . . I am quite clear as to the cutting of the hair."

From the worst wound (it being indeed where were several of those "which cannot be separated") a few fragments of bone of considerable size were taken; and from just within the external opening of the wound some chopped hair, mixed with the mangled tissues there, required removal. The injuries to the bones, including depressions, were estimated to be within an irregular space of about three inches long and nearly or quite two inches wide, somewhat semicircular at its upper or widest part. The external wounds or cuts, also, with one or two exceptions, particularly one in the occipital region (diagram at *c*), were within the limits of such a space.[1] There were no wounds on top of the head, or any other part of the body.

Now, it is evident that a first blow must have instantly stunned and paralyzed this woman — else there would have been movement of her body or derangement of clothing, of which there was neither. This blow may have been given by a bludgeon, a mallet, or a hammer of suitable size, form, and weight. Such blow repeated would naturally extend the fractures, comminute them, and cause any amount

of depression in the bony skull. But open wounds in the fleshy scalp by such instruments would as naturally have crushed or bruised edges (not the linear cuts here present) and the blows that made such wounds would have caused a spattering of blood all about — not the free bleeding which in this instance blanched the victim and saturated everything near by.

To account for the fractures and depressions then did not seem so very difficult, — any heavy club might answer. But what produced the curved and curiously situated incisions was a more difficult problem; and experts, professional and lay, called upon to solve it, as well as detectives and friends, all failed to suggest an adequate solution.

Several days after her admission, Dr. Cowles, superintendent of the hospital, called me in, as a consultant, to look at these wounds, to see what I could make of them. The parts had been shaven and fomented. The surface of the skin was quite smooth and uniformly convex — still notably swollen — the swelling covering rather more than the space originally thought to include the injuries to the skull bone. Some of the cuts near the ear gaped a little, but the others were generally in a satisfactory condition, and all had the appearance heretofore described. After hearing the whole story, and a careful consideration of the matter in all its bearings, I suggested that such wounds required a sharp instrument (as all admitted), and that the deed had been done by a mechanics' inch-wide *gouge*, — a tool resembling a chisel, but having, instead of a flat, a "hollow" cutting blade, a longitudinal third or trisection of a cylindrical tube. This is bevelled off, like a chisel, to a cutting edge, which in this way becomes curved or crescent-shaped. If the corners also are ground off, as on turners' gouges (*vide* fig. *inf.*)[2] the cutting end partakes of a rounded, spear-like form, and presents a drawing edge to whatever may be brought in contact with it. Hence it might cut hair almost as easily as a razor. Its handle is usually nearly or quite cylindrical, and of firm hardwood. Thus the tool might be just the club for heavy blows, if held by its metallic end, while its cutting edge would most certainly make wounds like those in question.

[1] The following diagram may assist in forming an idea of the number, nature, and situation of the curved wounds in the scalp; and also of the location of the injuries in the skull, at *a*, *b*, and *c*, as seen afterward in the specimen. Most of the heaviest blows, with the cutting end of the weapon, excepting that at *c*, must have been in front of the upper lobe of the ear, towards *b*; that is to say, where the skull was much cut through, where "brain protruded in a mangled state," and where fragments of bone were taken out. The temple" was evidently aimed at by the assailant.

[2] The figure below represents the cutting end of a turners' gouge, — showing its curved shape, and the rounded outline of its edge.

Such an instrument had not been thought of; but the suggestion evidently made an impression; for, on the next day, Dr. Cowles came to my house, bringing a turners' gouge, of inch-wide blade, a new one procured from a shop as a specimen by a police officer who wished to know whether that was the kind of instrument I had spoken of, — as it certainly was. The tool brought to me was nearly or quite two feet long — its inch-wide steel or cutting portion and its handle being of about equal lengths. Its handle was a heavy billet of hardwood, smooth, cylindrical, slightly ovoid at the end. Such a tool usually weighs thirty-five ounces, at least a pound more than a policeman's billy. Held by the metallic portion, a blow, given by it as with a club, would be quite capable of crushing in a skull and instantaneously stunning a victim to unconsciousness. Indeed, this would be almost inevitable; and without necessarily breaking the scalp. Repeated blows would have the effect heretofore indicated. This done the operator, without removing his hand, but by simply turning the tool nearly or quite vertical, with edge downwards, could stab the fleshy parts as rapidly and as many times as he chose, before the victim could have time to revive or even move. He could do this after premeditated intention, or on the impulse of the moment, to thoroughly complete the deed. Such stabs would make clean-cut and curved or crescent-shaped wounds naturally turned in the direction of those found; and when the instrument was driven with force it would not be apt to slide or make grooves in the flesh, as a blunt tool would; and might pass directly through the already comminuted bone into the brain itself.

As the skull injuries showed that they could have been made by the handle of a gouge such as that brought to me, so the flesh wounds indicated the blade of a similar instrument. Indeed, Dr. Cowles had already tried the cutting end of the tool he had with him, and found that it would fit the wounds exactly.

Thus the problem seemed to be satisfactorily solved.

Dr. Cowles then went on to say further, that among those interested in the woman was a young mechanic, who was, in fact, so tremulously anxious about her possible recovery as to excite suspicion, and induce the surveillance of the police. Since my visit to the hospital this man had been taken into custody. Proving to be a turner by trade, his workshop and tool-chest had been searched. The chest contained the usual tools, having a series of gouges complete, with the exception of the inch-bladed one. That was missing! The arrested man could not explain its absence, or give any account of what had become of it. He could not even tell when he had used or seen it last; and it was too large a tool to be lost without notice. These were rather damaging circumstances, but he stoutly asserted his entire innocence of the whole affair; and no other evidence was ever found against him. He had, it appeared, known the woman for some length of time, and had always seemed to be anxious for her welfare.

The woman did not in any way connect him in the matter, nor even recognize him; in fact, she was never able to recall the assault or any thing or person of the evening previous — an ante-accident oblivion not uncommon in those who have been severely stunned. The detained man made out an *alibi;* and was subsequently set free. He was generally accounted guiltless of the assault. I am not aware that the missing tool has ever been found, or its loss accounted for.

(As merest conjecture, in solution of this part of the mystery — possibly the man who with "horrid oaths" had threatened vengeance the evening before the assault, while in search of a club, may have robbed the chest of this tool — a very natural thing for a mechanic to do, and not unnatural in anyone on felonious intent. This may have suggested itself more readily to him if he knew the owner was an intimate of the threatened woman, as in such case the missing tool would tend to divert attention from himself and to turn it upon another man. Besides, the carrying a tool would not attract notice; whereas the possession of a club might arouse suspicion. The deed done, he could easily throw the tool into the waters of the dock near by, nevermore to be seen of men. There was, moreover, as rumor had it, an unaccounted-for disappearance from the neighborhood of a man quite competent to all this.)

The injured woman, after a protracted convalescence (during which the paralysis gradually disappeared) and a residence for a time at an asylum, at length regained her usual health and sanity. Before she was discharged, however, she declared her fixed determination to return to her old mode of life; and was soon lost sight of, except by the local police of her own immediate neighborhood.[3]

In May, 1876, nearly two years afterward, a condemned murderer, a few days before his execution, made a "confession" of many of his misdeeds, and claimed this assault as one of the number. He stated that by chance that evening he had met upon the street this woman, before unknown to him; that he went with her to a restaurant; thence to her house, and passed the night there; that, in the early morning, while she was yet sleeping, he pounded her on the head with a hammer, and then left her for dead. He further stated that the hammer might be found buried in the earth in a cellar he had access to at that time. He had had other things there, for murderous purposes, awaiting opportunity. The finding of a hammer gave credence to the story, which was pretty generally acquiesced in. But having had much to do with the case for which this man was to suffer (his last victim having been my patient), I distrusted the narration. Yet what motive, it may be asked, as it has been, for a man so situated to make misstatements? Although now concerned with facts, not motives, here is one among others, quite conceivable. At about that time, in another case, a death-sentence was delayed and a commutation expected (afterward actually granted) on the open avowal of murders and other revolting crimes, — on the ground that "irresistible impulse," or something of the kind, had rendered the villain *not responsible*. More than one murder was

[3] Dr. Edward Cowles, now superintendent of the McLean Asylum for the Insane, at Somerville, Mass., kindly permits me to say, that to the best of his knowledge and belief the case in my paper, so far as it came under his observation and cognizance, has been related by me in a true and faithful manner.

chargeable to this last convict. A long list might save his *life*, if his philanthropic sympathizers (after having denounced his sentence as unmerited and too hasty) could be induced to urge upon the government the plea that "he couldn't help it." It would have been the venture of desperation; but it was too late.[4] He soon became "much mixed," and finally broke down.

As to my patient, I had, as her murderer at last acknowledged, given in open court more correct details of the deed than he was able to recount when, in sight of the gallows, he attempted a narrative of his now admitted crime, — admitted to his amazed legal defender, whom he had deceived, up to that moment, into full belief of his innocence.

In regard to the injured woman, his statements were so defective, or so at variance with my observations as a medical man, that, for myself, I soon became convinced that he never had anything whatever to do with her, unknown to him, as he admitted, up to the day of the assault.

But the hammer! It was (I have seen it), a smiths' hand or riveting hammer,[5] with circular face of seven-eighths of an inch in diameter, not very sharply defined at the edge, but enlarging almost at once into a square form of an inch and three-eighths diagonal line; weighing only rather more than a pound, handle and all; not very likely on a first blow to completely stun in an instant, and thoroughly paralyze one struck by it, or to cause, with its small face, large fractures or depressions in the skull, or any fracture at all without leaving small, local, pulpy bruises in the scalp where struck, and not a uniformly smooth swelling as in this case. The *pein*, or wedge-shaped end of such a hammer, if the blow were of sufficient force, might cause a fracture, but then the wound left in the scalp would be a *straight*, mangled furrow or indentation. In like manner its round face would have a soft or pulpy and somewhat cup-shaped depression. If an open wound of the full size of its face could be so made, it would be circular, of course; but if less complete and of an inch in length (more than the diameter of this hammer's face), it could not be of a lesser arc than a semicircle. † One, or two such wounds segregate, might be *imagined*, perhaps, but half a score or so would be clearly impossible. Now, the wounds we had to deal with were crescent-shaped, not semicircular; were sharply defined incisions, all of equal lengths, variously inclined and running into or crossing each other, and in themselves hardly conceivable as the work of a hammer, or as made by anything else than a sharp, cutting instrument. Besides, no hammer's blunt face could be forced into and through the skin, except at an angle, and then the opening would be bruised down on one side and crushed off on the other, according as the instrument slipped, as it inevitably would more or less, on a rounded skull. Furthermore, we repeat, wounds made by a blunt tool might spatter their blood, but not set running so many freely flowing vessels. Bruised wounds do not bleed like incised ones. Again, and fatal it would seem in themselves to the "confession,"—

(*a*) No hammer, however keen its circular face-edge, or other blunt tool, could make such "sharp" *cuts* in and through the mass of hair this woman had, — no, not one such; much less a score; (*b*) Nor is it possible, supposing a human arm had the power, that a hammer-head, being only one inch and seven-eighths in length from its face to the hole for its handle, could be forced through such hair, scalp, and skull, into the brain to a depth in all of "fully two inches," without making a much larger opening, carrying in to the very depths hair, flesh, and fragments of bone, and leaving a very different state of things on the outside from that here found.

All that was done, however, could have been easily effected with a turners' gouge.[6]

Not long ago, March 20th, 1889, fourteen years after the injured woman left the hospital, a notice appeared in the newspapers that her body had been received at the morgue. I immediately called on Dr. Harris, medical examiner, who at once, with most courteous readiness, offered all facilities possible at so late a period. He had not known anything of her previous history; but had been told that after a prolonged drunken debauch, of which she had had many, nature giving way, she fell into a state of exhaustion, and in a few days thereafter had a painless and peaceful death. The cause of death had been officially reported "alcoholism."

Even in the grimness of her present surroundings and after such a life she was not ill-looking. Her face and features were not disfigured. She had "never had disease," except from alcohol, and was not wasted. Her head-of-hair was quite extraordinary in abundance, great length, softness, and glossy blackness. It had been well cared for; even the officials of penal institutions had respected it; and, contrary to their usual custom, had left her in full possession.

There had been an autopsy, and everything had been replaced in proper order; not then to be further disturbed. I sought out, however, the external scars in the scalp — an important matter. They were not at first easy to find on account of the thickness of the hair. They were there, nevertheless; and, except near the ear, where was a wrinkled group, they were delicate, linear, crescent-shaped scars, unmistakably the result of clean cuts, or incisions healed by first intention, — not of bruises. There could be no doubt in the matter.

Some weeks later I had a chance to see the "specimen," — deprived of most of its integuments. Looking at it in front, a general depression of the middle of the left side, as compared with the right,

[4] This supposition is not necessary to the argument, and perhaps it implies too great facility in expedients; but a man who could thoroughly hoodwink his friends and advocates at will, could readily take a new tack when convinced that the one he was on was soon to prove fatal.

[5] A friend reminds me that the murderer said that he used a plasterers' (*i.e.*, lathers') hammer—quite a different tool from that found; an instance of his inability to give details correctly. The hammer, as found, was so defective and weak in its handle, where attached to the metallic head, that a very feeble blow would have broken its head off.

[6] A small matter, perhaps, but tending to show the kind of instrument used, — almost all, if not all, the curved wounds had their points forwards or somewhat turned diagonally upwards, precisely as if made by a gouge held as one, when about to strike such blows, would naturally hold it — at its middle near the junction of the handle, with the tips of the fingers resting high up in its metallic, "hollow" part.

was quite evident; and this occupied about the space estimated in the first examinations at the hospital. Such a uniform and shallow depression suggested the result of blows by a weapon of considerable size, without angular projections, — a smooth club, most probably.

On side view, about two inches above the anterior third of the zygomatic arch, there appeared evidences of former fractures (diagram, at *a*). From a point on the frontal bone near the parietal several lines of old callus radiated at acute angles as from a centre. Between two of the uppermost of these was a double triangular prominence about an inch long and quite an inch and a half or more wide as it diminished off towards the base.

Very likely the fractures at this place came from the first blow the woman received from her assailant.

On, or just above, the level of the zygomatic arch, there was an oblong opening in the skull — beginning at the largest portion, just in front of the anterior part of the temporal ridge, and extending forwards about two inches (diagram, at *b*). The upper and lower bony edges of this opening, irregular in outline, were not rough, having been smoothed off naturally in progress of time since the injury. The lower border seemed to be of two nearly equal lines, each very slightly curved and joined together at an angle, open upwards, of about a hundred and twenty degrees. The upper border of the opening was rather more irregular, but equally smooth. The anterior limits ended in a point, almost, while the posterior or aural portion was three-fourths of an inch, or more perhaps, across. From this space undoubtedly came the fragments of bone removed at the first examinations. Here too, near the ear, the finger could be passed into the brain, but no hammer of the size and form of that found could have ever made an entrance through such an opening. A gouge could have done this, and easily have shaped the lower border of this cavity.

On the occipital bone, about three inches behind the meatus auditorius, was (at *c*) a well-marked curvilinear depression of about an inch chord, which, with a slight ridge inside, gave strongest evidence of a former wound by an instrument that had gone completely through the skull at this point. This was where (in Dr. Cowles's trials, before mentioned) the gouge would most exactly fit the fleshy wound; and the prolonged depression of the enclosed fragment of skull showed with what difficulty the tool must have been wrenched from its impackment in the bone. Now, indeed, if any one can conceive of anything better adapted to produce such a wound than a gouge, he must have greater powers of imagination than I can lay claim to. Even with such an instrument the blow must have been given with very great force. Not to insist that, in the position the victim was lying, the blow of a hammer in the hand of an assailant, if it made a curved indentation, must have made one in a different direction, — no hammer-head, even if held as a punch and struck by a sledge, could be driven through all the coverings of the skull and the skull itself at that place, and simply cut out, or force in, a circular, or as in this case an almost semicircular, fragment. A general crush of all the neighboring parts would be inevitable. A small hammer in the single hand of one person would seem wholly out of the question.

There did not appear to be anything else in the "specimen" attributable to the assault now under discussion.[7]

To recapitulate, — it appears from the length and width of the space involved in the fractures, and the depressions being in the outer table chiefly, that the victim had been struck by a club of some kind, — one of considerable size, and smooth also, inasmuch as the scalp was not laid open by it;

That, instantly stunned and paralyzed, her motionless insensibility permitted other blows, and the infliction of any number of open wounds;

That the wounds actually made, a score or so scattered or inseparable, were curved or crescent-shaped, with clean-cut edges, the little points, at the crossing of any two, whole and clearly defined, not bruised; that these wounds were of nearly equal size, each a full inch in length; and, further, that they were cut through thick hair "quite sharply," and through the scalp also, in one or two instances going quite through, and deeply into the brain; all evidently done by some kind of sharp-edged instrument;

That these wounds bled freely, as cut wounds generally do;

That a turners' gouge fulfils all the requirements of the case; while the hammer utterly fails in regard to the open wounds, and, as we think, in every particular.

Such are the premises; and such the offered solution.[8] An adequate explanation, however, ought to be enough to hold against the improbable, or the defective.

To some persons the circumstances attending the "confession" may seem to add credibility to the murderer's story, but they should not. The confession of criminals, even when without motive and only tending to increase their infamy, are not received by courts of justice unless supported by other and more trustworthy evidence. Dying persons, in their feeble and imperfect utterances, seldom fully know what they are talking about, as momentary revivals often prove. In the partial delirium of weakness, as in half-sleep, a person striving to say one thing may utter something very different from what he wishes, semi-consciously, and in spite of himself. Last words, ordinarily of little moment, should be construed with caution, for too seldom can they bear the interpretations one would gladly give to them. Death-bringing illness, while killing the body, generally, even where and when least expected, clouds or nearly obscures the

[7] There were three little depressions in the outer table near the vertex, two on one side of the sagittal suture and one on the other side, — as if it were at the corners of a right triangle. They were each capable of holding half a large pea, flattened. They were out of the reach of a weapon of any kind as the woman was then lying; and, as there were no wounds of any kind in that region when she was admitted to the hospital, they could not have had anything whatever to do with this assault.

I have the support of the highest authority in saying that there is nothing in the "specimen" inconsistent with the theory that a gouge was the instrument used by the assailant.

[8] Its elucidation an after-thought — else more thorough in details — incited by the last notice in the newspapers of the woman and her avowed assailant.

intellect, and fills the mind with baseless delusions, while the crushing terrors of impending destruction seem at times to start up in a culprit's mind remembrances of crimes which he never committed.[9] What wonder then, that, broken down by despair, the last straw of hope floating away, with mental powers utterly demoralized,[10] a doomed man, with or without rational motive, magnify his many misdeeds, assuming the acts of others which he had gloated on, and incorporating them with his own.

At all events, this portion of the murderer's "confession" I did not believe at the time. I do not believe it now. Facts in the case disprove it.

N. B.— After reading my paper a friend called my attention to an article in the London *Lancet* (Apr. 20, 1889, p. 819) wherein the writer asks, "Are most dying declarations unreliable evidence, and how may we differentiate them?" and then says, in answer, "If a human being be aboulic . . . . if suffering from extreme nervous exhaustion through terror or otherwise . . . . his [dying] statements are unreliable as evidence, ... and the sooner medical jurists insist on the alteration of the position and value of such testimonies the better it will be for society and for mankind."

THE MOVEMENTS OF THE LOWER JAW.

BY CHARLES E. LUCE, HARVARD DENTAL SCHOOL.

THIS paper presents the results of certain original investigations conducted in the physiological laboratory of the Harvard Medical School under the direction of Prof. Henry P. Bowditch. The results obtained are interesting, as they indicate the exact movements of the jaw, and prove that certain errors exist in all descriptions of this articulation as given by the eminent anatomists and physiologists.

These discrepancies may be briefly noted as follows:—

Monro[1] wrote, "that the mouth could not be opened, if the lower jaw was protruded, without withdrawing it from its advanced position;" this is clearly incorrect, as will be indicated later.

Ferrein[2] was quite accurate in his description, but he wrote that "the condyle advances under the eminence;" in many cases it goes under it and mounts the other side, which he omitted to say.

Humphrey[3] falls into the same error and said that "the condyle advances upon the glenoid ridge and should not go quite to the summit," which in many cases it certainly does.

Morris[4] was in error when he wrote that the condyle itself never reaches quite so far as the summit of the glenoid ridge.

Küss[5] wrote that the lower jaw, as it rises and falls, represents a lever moving around a supposed axis centred at the condyle, which remains in the glenoid cavity in small openings; and in greater separation the supposed axis is placed at, or near, the dental foramen; this is also incorrect, as will be proven later.

Quain[6] states "that the condyle rests on the convex root of zygoma when the mouth is opened. As stated above, in most cases it advances farther forward than he states.

The error of Gray[7] is in the statement that in openings of slight extent, the condyles simply rotate on a transverse axis against the cartilages, whereas the condyles begin to move forward simultaneously with the beginning of opening. Again, he says the condyles simply "glide on to the articular eminence."

The first requisite in the study of jaw movements is to move the jaw and get a permanent record of the movement; the method used was the photographic, the same as that used by Marey and others, and may be described as follows: a bright silver bead was fastened to a wooden pin or dowel, which was firmly inserted between the inferior central incisors; with the subject in a strong sunlight, so that a bright spot should be reflected from the bead, a pure profile or side view was photographed, and the sensitive plate was exposed during the opening of the mouth; the bright spot reflected from the bead during the motion was continuously photographed and its excursion recorded on the negative as a line, giving the actual movement of the place upon the jaw to which the bead was opposed.

The earlier experiments dealt solely with the simple tracing at the symphysis, and while the results obtained with one bead were both instructive and interesting, the more valuable results were found by getting the relative movements of condyle, angle, and symphysis; to get tracings at these points, a light framework was constructed, which simply reached around the face from the lower incisor teeth, to which it was securely fastened, nearly to the ear; adjusting devices held bright beads which could be placed directly opposite the condyle, angle, and symphysis; the photographing took place as before, each bead making its tracing.

FIG. 1.

[9] "An instance of remembering events that never occurred."—H. W. B. on testimony in another noted case.

[10] A recipient of another part of the "confession" says of it that it was "true so far as a person, with a mind so thoroughly demoralized as his had been, could make it." In fact, it is to be surmised that his statements generally would require corroborations from other testimony.

[4] Anatomy of the Joints, Morris.
[5] Lectures in Physiology, Küss, Duval.
[6] Quain's Anatomy, 1883.
[7] Gray's Anatomy, 1887.

Figure 1 shows the device as applied to a skull; the pin is inserted between the lower front teeth, two of the bright beads being adjusted directly opposite the condyle and angle, the other in front of the symphysis. It is apparent that the jaw and device will move in concert, and that the movement of the beads is, in fact, the same as that of the points opposite to which they are placed.

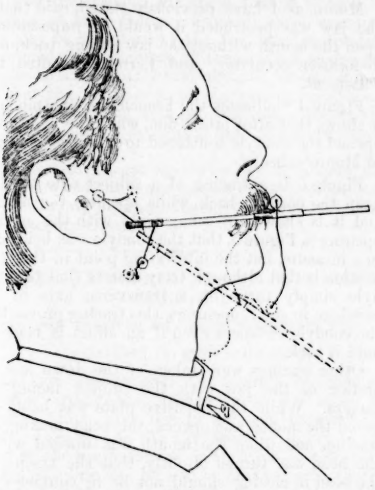

FIG. 2.

Figure 2 represents the tracings as taken at the three points mentioned.

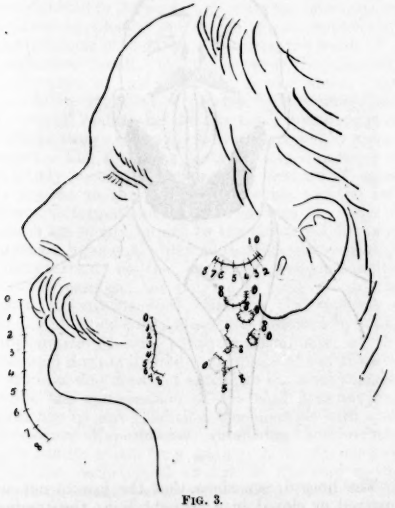

FIG. 3.

It now becomes necessary to indicate the methods by which the several tracings were subsequently studied. The picture was enlarged in outline by optical projection, and the tracing of the opening at symphysis was subdivided into convenient spaces; then, by means of dividers, corresponding points in the tracings at condyle and angle were determined as follows.

Referring to Figure 3, it is evident that the distance between the point marked 0 in the tracing at symphysis and the point marked 0 at the condyle does not change, inasmuch as both points are attached to a device which does not change its length; and though these points may seek different positions when the mouth is opened, the distance between them remains the same; and we find the ends of the tracings at 8 to be the same distance apart as at 0, the beginning. If the dividers are set at the proper distance, we can find, by simple measurement, how far the condyle moves in a given movement at the symphysis, and the motion of the angle is worked out in the same manner. The numbers on the tracings in Figure 3 indicate the positions occupied simultaneously by the various points of the jaw, the movements of which have been studied.

The tracings at all points in the jaw are readily understood, if we regard their motion as the result of a combination of a uniform downward and backward rotation round the condyle, with a forward motion of the condyle itself in a curved line, with the concavity upwards, always bearing in mind that this movement of the condyle is, at first, slow, then more rapid and subsequently slow again. It is evident that points in the immediate neighborhood of the condyle will have a movement differing very little from that of the condyle itself, while at more distant points the backward rotation round the condyle will be relatively more prominent, because the motion is on the circumference of a larger circle.

The tracings in Figure 3 illustrate this point. It will be noticed that the tracing nearest to that of the condyle is, like the latter, a curve with its concavity upward, but at the beginning and end of the motion, where the movement of the condyle is relatively slow, the rotation round the condyle is able to impress its backward motion upon the tracing. In studying the motion of points in the ramus, successively more and more distant from the condyle, we observe that the backward rotation becomes more and more prominent as a factor, and the forward movement due to the gliding of the condyle round the articular eminence less and less marked. The fact that this forward movement is most rapid in the middle of its course explains the loop-like character of these tracings, which is retained even so far down as the angle of the jaw.

By referring to Figure 3, it will be noticed that the condyle begins to move forward immediately, and even in a small opening of the mouth it performs quite a considerable excursion, contrary to the assertion of Gray and others to the effect that in small openings the condyles simply rotate on a transverse axis against the fibro-cartilages.

Again, it is stated by Morris, Humphrey, and others that the condyle never quite reaches the summit of the eminence; most of the tracings show that it does reach the summit and even be-

gins to mount the anterior side, as may be seen by Figure 3.

There are, however, exceptions, and it seems necessary that any assertion as to the action of this articulation should be qualified by the statement that there is considerable individual variation in

FIG. 4.

the relative movements of condyle, angle, and symphysis.

The idea of Meyer[8] that the jaw is suspended or hung in its lateral ligaments is substantially correct,

FIG. 5.

[8] Die Statik und Mechanik des Menschlichen Knochengerüstes. Leipsig, 1873.

and we can readily see that in moderate opening, when the condyle advances, the movement of the angle is comparatively slight, but when the capsular ligament becomes tense the condyle is kept from farther anterior movement and the angle goes back, as may be seen in Figure 3, the jaw swinging from the attachment of the lateral ligaments on the temporal bone.

Monro, as I have previously stated, said that if the jaw was protruded it would be impossible to open the mouth without the jaw sliding back, or a dislocation occurring, and Ferrein disputed this statement.

Figure 4 vindicates the Frenchman, inasmuch as it shows that after protrusion, when the mouth was opened the condyle continued to advance, contrary to Monro's theory.

Figure 5 is a tracing of a subject who tried to keep the condyle back while opening the mouth, and it is shown, by comparison with the normal opening in Figure 3, that the condyle was held back in a measure, but the interesting point in this connection is that although Gray asserts that the condyle simply turns on a transverse axis in the cartilage in small openings, this tracing proves that the condyle advances even if an effort is made to hold it back.

Other tracings were taken of the down and up motion of the jaw with the subject facing the camera. While the sensitive plate was being exposed the mouth was opened, the bead making its tracing, and when the mouth was opened widest the head was turned slightly, that the tracing of the bead in closing should not be in contact with the opening tracing.

FIG. 6.

The lines drawn show that the jaw is not depressed or closed in a straight line; the tracings taken contain several curves, which will vary with the same person at different times, on account of

the extreme mobility of this articulation and the fact that the condyles do not advance synchronously.

These tracings are interesting to dentists, inasmuch as they show what has to be contended against in taking the "bite" preparatory to the insertion of an artificial denture.

To conclude, as Ferrein said one hundred and fifty years ago, the movements of the lower jaw are not well understood, and much that is written of them is at least faulty. Probably some inaccuracies may be explained by the fact that anatomists have made too much use of the cadaver to demonstrate the actions of the articulations, whereas it may be that the contraction of the various muscles co-operating with and antagonizing each other is the important factor in determining the exact movements of the jaw.

If these investigations throw any light upon the movements of the lower jaw, or awaken an interest in the further study of them, something will have been accomplished.

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND E. G. BRACKETT, M.D.

PARALYSIS IN POTT'S DISEASE.

Elliott[1] has considered, in a careful and comprehensive article, the mechanism of the lesion or lesions which give rise to pressure paralysis in Pott's disease. As the old theory of injury to the cord by the encroachment on the canal by the crumbling vertebræ was seen to be unreasonable, by the fact that the degree of deformity does not materially influence the occurrence of paralysis, and also that specimens often show no encroachment on the canal, however much the direction was altered, attention was directed to the cord; and after the observations of Michaud, Charcot, and others, it was accepted that the paralysis was due to a myelitis, the result of a mechanical lesion. Of late, however, the inflammatory nature of this lesion has been doubted. Erb speaks in favor of a process of softening, and Strümpell claims that he has never found signs of inflammatory change in cords compressed by spinal caries. The following facts are urged in favor of a purely mechanical cause: A mechanical cause is present in the diseased vertebræ, and the tendency to formation of abscess cavities, the walls of which are partly formed by the thickened dura and anterior ligament, which have undergone a change characterized by the name of pachymeningitis externa caseosa; the bulging of this is into the canal toward the cord; clinically, the appearance of a gluteal or psoas abscess is followed by a disappearance of the paralysis; the site of the diseased dura is limited to the place of the diseased vertebræ, and does not extend to its inner surface, while the examination of the cord does not give evidence of any condition incompatible with compression. Experiments producing compression give results which from analogy favor this view — that the pathological change in the cord is the result of mechanical pressure only. The following summary is given: —

1. We have a simple mechanical process in the form of an abscess cavity, thickened dura or bone.

2. The inflammatory process is invariably a limited one, the inflammation of the dura being limited exactly to the site of the diseased vertebræ, showing no tendency to extend in the membrane — Nature's protection.

3. The ventral or medullary surface of the dura, at the site of the lesion, is almost invariably normal.

4. The pressure lesion is simply a mechanical one, manifesting no tendency to involve the spinal cord, through any inherent specific character of the carious process — a simple, bland mechanical lesion, and the damage it does commensurate with pressure exerted.

5. Pathological examinations have in the majority of cases necessarily been limited to old cases where the lesion had existed for a very considerable period, and such examinations usually revealed the cord largely converted into connective tissue, at the site of the lesion.

6. The presence of sclerotic tissue at the site of compression is no evidence that the original lesion was of an inflammatory nature, since it is a well-established pathological law that throughout the nerve centres destruction of nerve tissues by processes degenerative or otherwise is invariably followed by increase of connective tissue.

7. Experimental physiology gives no evidence of an inflammatory lesion following experimental compression of the spinal cord.

8. Finally, a careful revision of the pathological findings, in carefully reported cases, reveals to us in the light of recent pathological knowledge but a very few cases (4) where we have reason to believe the lesion to have been inflammatory. The suppurative process had been a very virulent one, and the pia mater had become involved. In three of the cases the dura mater has been perforated.

There are certain cases which he claims would be folly to consider as due to either myelitis or compression as described. Such are those in which the paralysis is of short duration, or the recovery is very rapid. These he considers are due to the indirect interference with the circulation. The blood-supply of the central part of the cord is by small arteries, and the anastomosis is not free. The lesion in pressure paralysis is not deep, and the arteries, situated on the surface of the cord and nerves, are at a disadvantage. Also, it is known that the inter-vertebral foramina are filled with exudation material, and microscopical examination of the arteries shows a thickening of their walls. Thus there is ample opportunity for considerable interference with the circulation. Erb says that softening and necrosis follow after this interference reaches a certain degree. Also, if the venous outflow is hindered there may be hæmorrhage from the engorgement. In favor of this theory of vascular disturbance he gives the following statement of the points demonstrated:—

1. Loss of blood-supply to the spinal cord produces motor and sensory paralysis. This is the result of experimental physiology to that end.

2. Increasing interference with blood-supply to the cord produces gradually increasing paralysis.

3. The blood-supply of the cord depends largely

[1] Trans. Internat. Med. Cong., ix. 1887, iii. 363.

upon the reinforcing branches which pass through the inter-vertebral arteries.

4. These arteries course over the surface of the cord.

5. The symptoms of this form of paralysis arise from affection of the anterior rather than the posterior portion of the cord, of the superficial rather than the deep, and the pathological findings sustain the clinical picture.

6. We have further shown that the result of the interference with the blood-supply may be in all degrees, from partial impairment of function to complete ischæmic softening.

7. This form of paralysis complicates a lesion when there are inflammatory products pressing upon the nerves and arteries coursing through the inter-vertebral canals.

8. The clinical picture of the vast majority of these cases is satisfactorily explained by the variance of the vascular mechanism.

The following conclusions are given as embracing the etiological condition of this disease:

1. A lesion producing pressure paralysis is in certain cases of an inflammatory character, a true myelitis, manifest in either the parenchymatous or interstitial form.

2. The vast majority of cases, however, we believe are due to a mechanical lesion, of which the circulatory cause is but a variety, and that this is in the future to be made the basis of pathology, and will merit the place held by the inflammatory theory of to-day.

TREATMENT OF JOINT TUBERCULOSIS.

Gester [2] calls attention to two aids of antitubercular therapy, preventive and curative, which he considers do not receive the attention they amply deserve.

First — the ice bag, on the principle demonstrated by Koch, of the extraordinary sensitiveness of the bacilli of tuberculosis to slight variations of the temperature of the soil in which they grow. This depression of temperature does not kill the spores, but brings about an arrest of growth, during which time the general power of resistance can be strengthened, and the healthy tissues can throw up around the focus of disease a wall of protective tissue. The class of cases especially benefited by this treatment are those of purely synovial tuberculosis.

The second "consists in the early ferreting out and surgical evacuation of tuberculous cheesy foci located in the epiphysis of the bones entering into the formation of this or that joint."

In adults, owing to the difficulty of orthopedic treatment, especially of the lower extremity, he advocates early exsection, and sums up as follows: "In tuberculous affections of the joints of adults in poor circumstances, especially those of the lower extremity, early operations are indicated and justified; total exsections deserving the preference, as a rapid and lasting cure is most desirable."

In children with local articular disease he advocates removal of the diseased portions only. This removal should be very thorough, that no diseased bone may remain as foci of extension of the process. This is aided by continuous irrigation with strong solutions of corrosive. General infection from the mechanical disturbance of the joint, called by Koenig "operative dissemination of tuberculosis," should be carefully guarded against. In such situations where an Esmarch bandage may be employed, this is easily avoided, but with the hips and shoulders special precautions must be taken. Such are, the avoidance of all rough force, clean work with the knife wherever possible, and the use of continual irrigation whenever the scoop is used to remove granulations, carious bone, or cheesy matter.

Barker,[3] in an article on the operative treatment of tubercular joint disease, describes an instrument used by him, by which the diseased portions are detached and washed away at the same time. It consists of an ordinary scoop, the handle of which is hollow and opens into the concavity of the instrument. A rubber tube of an irrigator is attached to the handle, and a free flow of water can thus be directed at the point of operation, under the immediate control of the operator.

ARTIFICIAL AUGMENTATION OF THE GROWTH OF BONE.

Max Schüller.[4] The theory is based on the principle that increase of blood-supply is frequently followed by an activity in growth, as is often seen after chronic inflammatory processes, this occurring when the disease affects the diaphysis, but when the epiphysis, or interarticular cartilages are the seat of disease, a decrease in bone formation ensues. Langenbeck, Bergmann, Dittel, Tillmann and others have made observations on the regeneration of bone. Helferich, von Bidder, and Haab have confirmed them experimentally. Pathological increase in bone growth has more rarely been observed after fractures, in joint disease, etc., and only in children. Experiments show that irritation results in an increase of bone formation. This may be done by scratching the periosteum, insertion of pegs, or by an elastic bandage producing an artificial congestion, as recommended by von Helferich. Schüller produced irritation in bone by means of steel pins, which were driven into the affected bones and left in four or five days. The results were very favorable. These cases are given with decided improvement. One case was of infantile paralysis, one of resection of the ankle leaving a loose joint, and one of genu valgum. An increase of bone formation occurred in each, with an improvement in usefulness of the limb.

Schüller tried the elastic ligature in cases of infantile paralysis. He so applied it that it compressed the veins but not the arteries. In addition he employed massage, exercise, bathing, diet, etc. At first the bandage was allowed to remain only a few hours, but later was worn continually. Improvement occurred in all. In two cases reported there was an actual increase in the length of the bone.

RESECTION OF LONG BONES.

Arthur Neve [5] gives his results of resections of

[2] Trans. Med. Soc. N. Y., 88, 478.

[3] Brit. Med. Jour., 1889, i. 121.

[4] Deut. med. Zeitschr., 88, No. 99, from J. Med. Sc., Feb., 1889.

[5] Am. J. Med. Sc., 1889, Mar., 229.

shafts of long bones, about two hundred in all. The operations were for necrosis, more or less extensive, and in some cases the entire shaft was removed. The periosteum was carefully preserved, and in no case was there failure of reproduction of bone with useful limb, and only two cases were fatal. The primary resection is applicable to those cases in which more or less general necrosis is inevitable, and particularly for those cases of acute periostitis, sometimes called osteomyelitis, following fracture. The patients react quickly and well, even those reduced by long suppuration. The reproduction of the osseous tissue is usually rapid; in one case, in which four and a half inches were removed, the patient walked in a month.

Secondary resection, that is, of healthy bone, is on a different basis. In this operation the age of the patient and condition of the periosteum is to be considered as well as general conditions, as there is danger of too great interference, and a failure to obtain sufficient new bone formation, and in early operation on cases other than of total necrosis it is not easy to estimate the amount of bone that will be sequestrated. When there is considerable central necrosis it is better to remove a part of the circumference, as the cases heal much quicker.

After resection of the whole thickness of a long bone, shortening and distortion is to be guarded against.

(To be continued.)

Reports of Societies.

FORTIETH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION,

HELD AT NEWPORT, R. I. JUNE 25TH TO 29TH, 1889.[1]

General Session — Second Day — Wednesday, June 26th.

THE meeting was called to order by DR. W. W. DAWSON, the President, who called upon the Right Rev. Thomas U. Clarke, Bishop of Rhode Island, to offer prayer.

DR. WILLIAM PEPPER, provost of the University of Pennsylvania, then gave the address on general medicine.

It consisted almost wholly of a biographical sketch of Dr. Benjamin Rush, of Philadelphia, who was born in 1745 and died in 1813. He was surgeon-general and physician-general of the Continental army, and professor of the theory and practice of medicine in the Philadelphia Medical College. In 1785 he planned the Philadelphia Dispensary, the first in the United States. Dr. Rush was by far the most prominent of the doctors of the Revolutionary period, — so prominent, in fact, that he was to the American medical profession what Dr. Sydenham was to England. His fame rested chiefly on his great efforts in the epidemic of 1793, when he stood out beyond all his colleagues as the doctor whose practice most resembled the practice of the present day, although he treated fevers and phthisis by bleeding. His use of the lancet was compared with that of Dr. Sydenham and the present day, and the opinion given that in the earlier periods of disease it is a question if the practice of these older men was not, at times, better than the present. After considering the practice of Dr. Rush in the case of fevers, in which he advocated the use of cold water and dieting, Dr. Pepper spoke of his great abilities in other directions. In mental diseases he was a pioneer of rare sagacity, large wisdom, and enlightened humanity. His course in consumptive cases was referred to and his advanced views shown. In every way Dr. Rush was a pioneer in the field of medical practice, and the history of American medicine practically begins with and was for a time the history of Dr. Rush.

SURGEON A. L. GIHON, U. S. navy, chairman of the Rush Monument Committee, then read his report, starting with the statement that the committee could report no progress compared to their expectations, and, at the present rate, there was no hope even of any of the present committee ever living to see the monument. It was thought there would be no trouble in getting $40,000 if the doctors each contributed one dollar for the purpose. After five years the committee had but one thousand, instead of the forty expected. The history of popular monuments generally agreed, however, with this, the speaker quoting the Washington, Grant, Liberty, and other monuments to show how slow the American people were in such matters compared with the Old World. He made an eloquent plea for some decisive work, and announced that the $1 limit was dropped and larger sums would be taken.

During the morning $264.50 was received, one of the contributors being Dr. Earley, whose family physician Dr. Rush had been. Several propositions were made to further the work of collection, and it was voted to appoint a canvasser in each county to personally solicit.

Various amendments to the constitution were proposed, discussed, and rejected.

A resolution from the section of state medicine was read, stating it to be the duty of the United States and every other country to abolish sources of infection within their borders.

Third Day — Thursday, June 27th.

A communication was received from the Social Science Association inclosing a copy of resolutions passed by that association demanding a more thorough training for medical students, and petitioning the State legislatures for laws against incorporation of bodies unqualified to teach medicine.

The memorial was accepted.

DR. HOOPER, of Arkansas, offered the report of the trustees of the journal of the association.

The report showed that the weekly circulation was four thousand six hundred and thirty-three copies, four thousand three hundred and thirty-nine of which were sent to members of the association; the present edition was five thousand, and the journal was free from debt.

THE ADDRESS IN SURGERY

was delivered by PHINEAS S. CONNOR, M.D., of Cincinnati.

It was one of much interest, reviewing the progress of surgery in the past forty years, showing the triumphs of anæsthetics, of antisepsis, of

[1] Continued from page 650, vol. cxx.

internal operative surgery, whether in the abdominal, the thoracic, or the cerebro-spinal cavities, and indicating the probable conquests of the surgeon in the future — especially in regard to tuberculous and cancerous affections.

Dr. Connor brought his eloquent and hopeful address to a close with the following words:—

As we survey the advances, etiological, diagnostic, and therapeutic, made in the few years just past, that are of the scientific period, and consider, even in the most hurried way, the problems that are yet awaiting solution — problems relating to nature, origin, and treatment of the diseases and injuries of parts within the domain of surgery — what may we not reasonably anticipate as the future of our science and art! Accidents must occur, diseases will prevail, no matter how great the triumphs of preventive medicine. Surgical pathology is but in its infancy. Years ago it was declared that operative surgery had reached its climax. Yet since then operations have over and over again been done within abdomen, chest, and skull, upon the larynx, throat, and spinal cord, that in boldness of conception and brilliancy of execution have no parallel in the history of medicine. The end is not yet, nor will be while, the world over, there are active minds and cunning hands busied with the determination of the existence and extent of surgical affections, and ready and able to remove them, aided more and more by labors of investigators in many departments of science, general as well as medical. Year by year he who may deliver the address on surgery will be able to report doubts removed, discoveries made, remedies employed, and operations done.

The next meeting of the association it was decided to hold at Nashville, Tenn., the third Tuesday in May, 1890.

The report of the nominating committee was accepted and the nominees were elected as follows:—

President, E. M. Moore, of Rochester, N. Y.; vice-presidents, J. W. Jackson, of Missouri; W. W. Kemble, of Minnesota; J. H. Warren, of Massachusetts: T. B. Evans, of Maryland; permanent secretary, Wm. B. Atkinson, of Philadelphia; treasurer, R. J. Dunglison, of Philadelphia; librarian, C. H. A. Kleinschmidt, of Washington, D. C. Trustees of the journal, T. O. Hooper, of Arkansas; Alonzo Garcelon, of Maine; I. N. Love, of St. Louis; W. W. Dawson, of Cincinnati. Address in medicine, N. S. Davis, of Illinois; in surgery, Hunter McGuire, of Richmond; in state medicine, A. L. Carrol, of New York. Chairman of the committee of arrangements, W. T. Briggs of Nashville. Assistant secretary, G. C. Savage, of Nashville.

DR. F. WOODBURY, of Philadelphia, offered a resolution, which was adopted, recommending the alteration of our patent laws in so far as these now favor foreign manufacturers of drugs.

A resolution from the section on state medicine was adopted recommending uniformity in State medical legislation; that a thorough preliminary examination, three courses of lectures, and an examination by the board issuing a license be required; the license to practise be recorded in the office of the county clerk; and that the licensing board be endowed with power to revoke a license on acount of immoral conduct.

DR. WOODBURY, of Philadelphia, moved that the members of the American Pharmaceutical Association be invited to seats on the platform, and that a committee be appointed to confer with the association in reference to the creation of a section of pharmacy and materia medica in this association, and to report on the second day of the next annual meeting.

SIR JAMES GRANT, of Ottawa, was presented and made some brief remarks.

Officers of sections were elected as follows for the ensuing year: —

Practice of medicine — Chairman, J. H. Musser, Philadelphia; secretary, Hugh McCall, Lapere, Mich.

Surgery and anatomy — Chairman, B. A. Watson, Jersey City; secretary, John B. Deaver, Philadelphia.

Obstetrics and diseases of women — Chairman, W. W. Potter, Buffalo; secretary, Joseph Hoffman, Philadelphia.

State medicine — Chairman, J. B. Hamilton, Washington; secretary, F. S. Bascom, Utah.

Laryngology and otology — Chairman, John O. Roe, Rochester; secretary, Frank H. Potter, Buffalo.

Diseases of children — Chairman, I. N. Love, St. Louis; secretary, E. F. Brush, Mt. Vernon, N. Y.

Dermatology and syphilography — Chairman, I. E. Atkinson, Baltimore; secretary, W. T. Corlett, Cleveland.

Oral and dental surgery — Chairman, J. L. Williams, Boston; secretary, E. S. Talbot, Chicago.

There was no election in the section of Ophthalmology.

SECTION OF THE PRACTICE OF MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

First Day — June 25th, 1889.

The section was called to order at 3 P. M. by the Chairman, DR. F. C. SHATTUCK, of Boston, who, in accordance with the usual custom, reviewed the progress of medicine in the past year.[1]

The first paper was read by DR. C. G. STOCKTON, Buffalo, N. Y., on

THE PASSAGE OF PORTAL BLOOD INTO THE GENERAL CIRCULATION, AND ITS PROBABLE RELATION TO TOXÆMIA.

The reader claimed, first, that the occurrence of inosculations between the portal and general systemic veins was to a certain extent normal; that these intercommunications might as anomalous conditions be extensive; that obstructive liver diseases, or peri-hepatitis, might result in the production of new anastomoses.

Second, that the blood of the portal vein was toxic in character, at times extremely so. The lower pressure of the blood in the portal than in the general venous circulation was held to be the reason of prevention of toxæmia in ordinary cases. In case of obstruction in the portal circle portal blood entered the systemic veins without filtering through the liver, thus inducing toxæmia.

Were it not for the action of the blood upon the

[1] See page 1 of this Journal.

substances which are carried into the circulation this would prove more disastrous than it does. The blood in health possessing the power of self-purification to a certain extent, serious toxæmia did not often follow until the integrity, the resistance, of the blood was diminished by long effort or by disease, and then toxicity was made evident by symptoms.

Reference was made to the coma of cirrhosis, to propeptonuria, glycosuria, and certain cachexiæ. The low pressure in the portal vein was proved by experiment of Prof. Julius Pohlman upon lower animals.

DISCUSSION.

Dr. William Osler, Baltimore, in opening the discussion, said he doubted if toxæmia in hepatic cirrhosis received its solution in this way. The collateral circulation, of which the reader spoke, was not a rarity, but a constancy; for the blocking of the channels in the liver due to cirrhosis must be met by collateral circulation; and in every case of cirrhosis whether symptoms occurred or not would depend entirely upon the degree of collateral circulation established. It was the counterpart of the narrowing of a valve in the heart; if compensatory hypertrophy occurred symptoms were slight. Most extreme cases of cirrhosis had been found post mortem without a single symptom in the individual's lifetime. In such a case a large proportion of the portal blood was passed into the systemic circulation. Furthermore, those still rarer instances of firm fibroid, obliteration of the portal vein, where all the portal blood had had to find its way for years into the systemic circulation, seemed quite opposed to such a theory.

Dr. W. S. Tremaine, United States army, thought a mistake was often made in thinking of the portal circulation and the portal system as distinct from each other. The portal circulation was a part of the venous circulation, the liver being interposed. The portal circulation contained blood which differed from that found in other portions of the venous system, and when the blood passed through the liver it passed through for certain purposes, many of which were not clearly understood. He thought these toxic symptoms were due rather to defective action of the liver in eliminating deleterious or in producing other products which might be necessary. He agreed with the reader with reference to his remarks on the blood. He was inclined to look upon the blood, not as a homogeneous fluid flowing through the blood-vessels, but as an organ capable of manufacturing certain substances which might be necessary to life, and capable of removing or destroying deleterious substances. Digestion, he believed, did not conclude with the liver, with the stomach, with the intestines, but was carried on in the blood. We were apt to be led into error by accepting certain physiological statements as facts, while they were often only theories.

Dr. J. H. Musser, Philadelphia, said that clinically the forms of coma he had seen in cases of cirrhosis of the liver, or after other liver derangements, he had explained either by the occurrence of cholæmia or possibly uræmia. The liver was a poison destroyer, and when its function was destroyed coma might arise from toxæmia.

The establishment of collateral circulation was something we should look forward to as offering relief to our patients.

In all the cases of coma he had seen there had been some determining factor prior to the coma disturbing the balance of the economy, as for instance pneumonia, which interfered with oxidation, or an extreme degree of congestion of the lungs or some other organ, some serous membrane particularly.

Dr. Hare, Philadelphia, expressed the belief that any capillary network was just as destructive of poisonous substances in the blood as the liver. Experiments seemed to show that the liver, so far as poisons were concerned, was nothing more than large capillary networks through which these poisons had to pass.

It seemed to him reasonable that the interference of oxidation in pneumonia might be a cause for some of these toxic symptoms, owing to the presence of effete matters in the blood.

In regard to the influence of the blood which passed from the portal vein into the systemic circulation in the production of poisonous symptoms we must bear in mind that if it contained peptones thoroughly converted by the gastric juice no disturbance would result, whereas semipeptones would produce very distinct toxic symptoms.

Dr. C. G. Stockton, in closing the discussion, said he did not deny that in cirrhosis and in other diseases involving practically occlusion of the portal vein no serious symptoms might occur. He did not wish to be understood as directing the paper towards cirrhotic coma, but he had used that as a marked illustration. He admitted that the inosculations were common, but held that portal blood did not flow into the systemic veins, except when there was obstruction in the liver, because of the low pressure in the portal vein. This low pressure was the only protection, he held, to the entrance of portal blood into the general circulation, and there must be present a condition producing portal obstruction to allow the portal blood to flow out in this way. If the liver had this function of acting as a capillary network and prohibiting some of the poison entering the blood, and the blood could overcome to some extent the poison that entered, he held that the low pressure in the portal vein was conservative, and that certain toxæmias from certain obstructive diseases of the liver occurred because this blood entered the circulation in a toxic condition and led to toxæmia.

Dr. G. R. Martine, of Glen's Falls, N. Y., read a paper on

A NEW PLAN FOR THE TREATMENT OF PNEUMONIA.

Dr. Martine alluded to the many general plans of treatment.

The first abnormal symptom after the premonitory chill was quickening of the pulse and increased flow of arterial blood, and in consequence a distention of calibre in the arterial vessels, overstraining of capillary walls, and extravasation of blood corpuscles. Reduction of the temperature at this stage would not hold in check this increased flow of blood to the lungs, which, if unrestrained, was sure to end in consolidation.

Now, the whole method of the new plan could be given in five words, viz., Hold the pulse below

80. Keep your fever thermometer in your pocket; it was of little or no use in pneumonia.

Death did not result from high temperature in pneumonia, but from high arterial action, resulting extravasation and consolidation and consequent heart-failure.

In holding the pulse veratrum viride had seemed to serve the reader best, yet he admitted that other arterial sedatives might in the hands of others act as well. If the pulse be held below 80 in adults or at 100 to 120 in children, with perfect vigilance, no further trouble need be apprehended; for in that condition there would be no extravasation, if no extravasation no consolidation, if no consolidation no hepatization, and if no hepatization no suppuration, mortification, or death.

Heart-failure in uncomplicated pneumonia would be a thing impossible, provided this plan be followed.

DISCUSSION.

DR. ATKINSON, Baltimore, objected to the claim made for veratrum viride in the treatment of pneumonia. Veratrum viride had undergone severe tests and had not, he thought, yielded the results claimed in the paper.

In pneumonia patients died not so much from filling up of the lung with blood as from failure of the action of the heart, and it was this failure that we must guard against in treating our patients. He did not think a remedy capable of depressing the action of the heart was one especially to be recommended in cases where the very condition of depressed heart-action was the one we must dread.

DR. HARE, Philadelphia, thought the great trouble in the use of veratrum viride in pneumonia was that the fact of two diametrically opposite conditions in this disease was lost sight of. In the first stage of pneumonia there was a perfect "rush" of blood into the lung due to over heart-action, and it was in that stage the veratrum viride should be given to abort, not to cure, the pneumonia. In the second stage, where the heart's action was weak, digitalis was indicated.

In regard to the poisonous properties of veratrum viride, there were only four fatal cases recorded. This was owing probably to its emetic action, and the emetic action was the element in the cardiac depression. When veratrum viride proved fatal it was through depression of the respiratory centre, not by depression of the heart.

DR. G. R. MARTINE, in closing the discussion, claimed that his plan was new in this, that no writer had told us when to hold the pulse and prevent consolidation and consequent heart-failure. Heart-failure would not come on in pneumonia if the patient were properly treated and the pulse held. When the lungs became filled with blood we began to get heart-failure. The right side of the heart, in trying to force the blood through, became fatigued. His plan prevented the filling of the lungs with blood and consequent heart-failure. He had treated pneumonia in this way thirty years, and he did not expect to lose an uncomplicated case of pneumonia any more than a case of toothache.

DR. JOHN H. MUSSER, of Philadelphia, read a paper on

SOME CLINICAL ASPECTS OF VOMITING.

Dr. Musser called attention to the mechanism of vomiting, saying it was a reflex act due to excitation of a vomiting centre situated in the medulla in intimate relation to the respiratory centre. Motor influences were transmitted from the centre to the abdominal and thoracic muscles, to the œsophagus and cardia, causing its relaxation, and to the pyloric end of the stomach, causing its closure. Excitation of this centre was made by impulses derived by afferent nerves from various organs of the body. It was shown that the vomiting may be toxic in origin, may be from organic change about the centre, as tumors, abscess, etc Lastly, it was reflex from affections of the brain and of various organs, all of which were detailed.

Attention was called to morning vomiting, and causes other than those usually mentioned were detailed, as in sewer gas poisoning; to vomiting due to subacute naso-pharyngeal catarrh, and to ovarian and uterine vomiting, etc.

Some special clinical aspects of vomiting were then detailed, and it was insisted upon that in affections of various organs vomiting might for some time be the only marked symptom, and particularly if the function or structure of an organ was not interrupted. Cases of pneumonia, peritonitis, intestinal obstruction, etc. were detailed, and vomiting that attends apoplexy described.

Regarding the relation of this symptom to cerebral hæmorrhage the following conclusions were presented: —

1st. That constant vomiting in the aged, painless, with or without nausea, with no evidence of indigestion or acute gastritis, the ejection composed of mucus or a watery fluid, was often one of the first symptoms of central hæmorrhage.

2nd. Such vomiting was not attended with the usual symptoms of relaxation and with the sthenic phenomena which usually attended apoplexy.

3rd. If the usual collapse symptoms occurred in a person of that age the vomiting was more likely to be due to a uræmic origin.

4th. If the respiration was altered in rhythm, or was of normal frequency or hurried, because of the intimate relation of the centre of vomiting and the pneumogastric centre, the cause was doubtless a central hæmorrhage. Hurried breathing attended the acute vomiting of other causes.

5th. The occurrence of vertigo was not of special significance.

6th. The prognosis was very grave in such cases.

Habit vomiting, so called, was then described.

DISCUSSION.

DR. C. G. STOCKTON, Buffalo, N. Y., said that one point particularly struck him, and that was vomiting in connection with naso-pharyngeal catarrh. He thought also that chronic gastric catarrh was a common accompaniment of naso-pharyngeal catarrh, and that vomiting in these cases in his experience had almost always been accounted for by the gastric catarrh.

DR. W. G. SCOTT, Ohio, said that in his experience patients who vomited at any time — in the midst of a meal or after a meal, etc. — always had some

trouble with the stomach, and frequently we had catarrhal condition, the secretions of the stomach changed entirely.

DR. I. E. ATKINSON, of Baltimore, read a paper on

SOME OF THE RARER AND GRAVER FORMS OF CINCHONISM.

DR. Atkinson devoted most of his paper to detailing cases in which cinchonism had occurred from the administration of rather large doses of quinine, also cases where quite marked symptoms had resulted from small and often-repeated doses. His general conclusion was that the physician should use caution in repeating the larger doses, owing to the risk of amaurosis and other symptoms indicative of poisoning by quinine. Oftentimes smaller doses were efficient, and it should not be the routine practice to employ large doses; and when large doses were indicated the use of quinine subcutaneously would be a good substitute, as the dose was much smaller when so used.

DR. HARE, of Philadelphia, called attention to one explanation why cinchonism did not result oftener from large doses of quinine; it was due to the fact that it often passed the pyloric orifice without being acted upon, was precipitated and passed out with the stools, not having been absorbed.

DR. W. G. SCOTT, Ohio, said large doses were by no means always innocuous, and were not always passed out without being dissolved.

In treating malignant intermittent fever small doses would not arrest the fever, and people had died, he thought, for want of a good large dose. He had never seen cinchonism or bad effects from the legitimate use of quinine. Such a remedy, however, which exerted such an influence upon the central nervous system, if not needed, might do harm.

DR. J. H. MUSSER, Philadelphia, said it had been found that ordinary cases of intermittent fever seen in the neighborhood of Philadelphia could be controlled with smaller doses than were formerly given. One grain three times a day had been found, by Dr. Osler's experiments, to be efficient in causing the disappearance of the changes in the blood.

DR. W. S. TREMAINE, U. S. army, thought the size of the dose depended entirely upon the locality and what one had to deal with. If the malarial poisoning was intense, large doses were indicated; if mild, small doses might suffice.

DR. ATKINSON, in closing the discussion, said he did not wish to raise a question against quinine in large doses, but simply that the administration of large doses was not without very serious danger, although bad effects were rare.

No doubt large doses of quinine often passed through the alimentary canal unabsorbed; and the old practice of giving a large dose of calomel before giving quinine was justified in that it cleared out the upper portion of the intestinal canal of its alkaline contents and kept the contents of the stomach acid, and thus facilitated the absorption of the quinine. When amaurosis resulted from large doses of quinine, although it might never be complete, yet it might result in such permanent damage to the eye that in his opinion only the greatest emergencies justified the lavish giving of this drug, and where large doses were necessary it was better to give smaller doses under the skin than enormous doses by the stomach.

DR. ROBERT T. EDES, of Washington, read a paper on

HYDRONEPHROSIS AND RENAL ATROPHY; ESPECIALLY AS RESULTING FROM FUNCTIONAL DISTURBANCES OF MICTURITION.

The ordinarily recognized mechanical causes of hydronephrosis were stated. Systematic authors admitted that there were cases not explicable by any of these causes.

Two cases were reported.

1. A boy with frequent micturition but probable retention of urine, who presented symptoms of interstitial nephritis, and was found, after death, to have a large bladder, dilated ureters, atrophied kidneys, and hypertrophied heart, no mechanical obstacle being present.

2. A little girl with albumen, casts, and pus in the copious, light urine was noticed to have some difficulty in micturition. After dilatation of the urethra the casts soon disappeared and later the albumen.

The back pressure of urine necessary to produce moderate hydronephrosis with renal atrophy was not great.

The bladder was a portion of the apparatus necessary for the discharge of the urine, and was not to be regarded simply as a passive reservoir.

In order that it might perform its function properly a certain balance between the nervo-muscular apparatus promoting the discharge (detrusor urinæ) and that restraining it (sphincter vesicæ) was necessary. If this balance was disturbed either by paralysis of the detrusor or by spasm of the sphincter, pressure was thrown back toward the kidneys and dilatation of the passages took place, followed by renal irritation and destruction of the parenchyma.

In the constantly recurring spasmodic action of the bladder in cystitis, with the consequent exaggeration of the intravesical pressure, the same thing might occur, with this modification, that the urine which was backed up being mingled with inflammatory products, the result was a pyonephrosis, rather than a hydronephrosis.

It is suggested that some cases of interstitial nephritis in the young, even when accompanied by hypertrophy of the heart and not differing greatly in symptoms from the disease which was more familiar in persons in middle life, might have a local origin in unrecognized causes of this kind, rather than the constitutional changes so prominent in the etiology of the Bright's disease of later years. A few cases were to be found in medical literature bearing on the subject of the paper.

SECTION OF SURGERY.

First Day — Tuesday, June 25th.

THE address in this section was by the chairman, DR. N. P. DANDRIDGE, of Cincinnati, on

THE SURGERY OF THE SPINAL CORD.

It is only within a few years that the surgery of

the spinal cord may be said to have come into being. The surgeon of a former generation never thought of opening the spinal canal for the removal of the effects of injury, or for the cure of disease. The method of treating Pott's disease by extension is also a modern method.

There are certain lesions, as tumors, where without an operation the surgeon is powerless to render aid. In Pott's disease simple extension sometimes works wonders; sensation and motion, previously lost, return after application of a plaster jacket and suspension. Instances were cited where a paralysis of eight months' duration was cured by this method; in one case the patient had been paralyzed for two years.

Resection of the spinal arches of certain of the vertebræ by relieving pressure (removal of a clot, of certain exudations, etc.) has often enabled the spinal cord to recover its functions.

Fractures of the vertebræ are not as fatal as they were once believed to be; 21% survive, and of this number 10% make a good recovery, while 11% are completely disabled. Extension has given good results in some cases of vertebral fractures; trephining has been attended with only partial success.

Of the various modes of extension, the hammock suspension had been especially successful in the practice of the reader.

In fractures of the cervical vertebræ any displacement should be rectified at once; in dorsal and lumbar fractures there may be a reasonable delay, and here suspension, with the plaster jacket, sometimes works wonders. Marked depression of the arches and laminæ calls for instant trephining.

DR. W. H. PANCOAST, of Philadelphia, spoke of the importance of extension in fractures of the spine. There are cases of fracture of the vertebræ that cannot be diagnosticated during life. Again, there are cases of death due to shock where the bones and ligaments are intact. Dr. Pancoast is confident, from many observations which he has made, that often in cases of hanging the person dies from shock without fracture; there is not even rupture of the ligaments.

The next paper was by DR. H. H. SMITH, of Philadelphia, on

CONCUSSION OF THE SPINE IN ITS MEDICO-LEGAL ASPECT.

The legal liability of capitalists and corporations for damages for neglect to provide for the safety of individuals who have entrusted their persons and their lives to their care may be seen to date from Lord Campbell's Liability Act in 1848. Since this time the various States of the Union have incorporated in their ordinances statutes making companies and corporations liable to damages for loss of business and time, for physical injuries sustained by persons through ignorance, carelessness, and neglect of officials or employees. Since then incalculable sums of money have been paid, especially by railroad corporations. Juries are almost certain to find against these corporations, and physicians have not always placed themselves in an attitude of impartiality when called to testify in behalf of their clients.

The reader believed that the professional opinions of twenty years ago on the vexed question of concussion of the spine are now utterly unreliable, nor does he think that Erichsen should longer be regarded as an authority on the subject. There has been a great advance in the knowledge of the histology (normal and morbid) and symptomatology of the spinal cord within the last two decades. He asked, "Does the so-called 'railroad spine' exist?" and while believing that there is such a theory as spinal concussion with no recognizable organic lesions, where only molecular disturbances are assumed to exist, yet he does not hesitate to affirm that such cases are extremely rare. Fraud is very common. According to Hodges' estimate, out of forty-nine cases thirty-six were proved to be fraudulent. Most cases are attributable in the last analysis to hysteria or malingering. The reader was of opinion that serious organic disease very seldom follows concussion; and if the symptoms were simply subjective, if there were no organic manifestations, as loss of sensation and motion, loss of reflex excitability, vaso-motor disturbances, muscular atrophy, he should doubt the existence of any serious injury. Any grave lesion of the cord will certainly be followed by objective symptoms, and these will ensue soon, in a few hours or days, not months, after the injury. He gave from his record-book instances in support of this statement, but here the morbid phenomena accompanied grave myelitis with softening, the result of the injury. He did not believe that jars from travelling, as when cars are coupled with too much violence, ever cause such lesions. A severe shock to the spinal cord may give rise to hæmorrhage, or effusion, to some form of myelitis with more or less paralysis and muscular atrophy, but in such cases we have something besides subjective symptoms for a guide. It is true, however, that sometimes a pre-existing neurasthenia may be awakened and aggravated, or a latent hysteria developed into active exercise. The physician should weigh well the probabilities of these conditions in any give case, as well as the chances of fraud and dishonesty on the part of the patient.

DR. HERBERT JUDD, of Galesburg, said that the question of concussion of the spinal cord had become a matter of business, in the pursuit of which ignorant or unscrupulous physicians in concert with knavish lawyers and dishonest laymen "bled" the railroad companies; millions of dollars had, in fact, the past twenty-five years been paid to settle claims that were for the most part fraudulent. For all this such authorities as Erichsen were largely to blame. Generally there are nothing but "subjective" symptoms to substantiate these claims. We ought always to suspect imposture where there is no paralysis, no muscular atrophy, or other objective manifestations.

This business is demoralizing society. It is by no means uncommon for a person with a reputation for honesty and truthfulness to "nurse" a really trivial injury into a permanent disability, and impose on even the wary physician; thousands of dollars damages are obtained, and the patient speedily gets well. People than lose confidence in the honesty and competence of physicians; and the medical profession is brought into ridicule. This matter of spinal concussion is largely a "bugaboo."

More people are annually injured by ordinary vehicles (as by upsets) than by railroads, but how seldom do we see spinal concussion follow; he doubted whether there be such a thing as spinal concussion as some authors have described it.

DR. WILLIAM BRODIE had seen so much of the unfairness and injustice of juries towards railroad companies, that he now advised railroad officials to settle instantly by a money payment whenever a complaint was made of injury received on a railroad by cars running off from the track, or in any other way.

DR. B. A. WATSON said that he did not believe in spinal concussion as Erichsen describes it. Is there such a disease analogous to concussion of the brain? If there be such a disease it is extremely rare. That the spinal cord sometimes receives severe injury from blows, falls, the force of a nearly spent bullet, the impact of sea-waves, etc., he fully believed, but in such cases there are generally fractures of vertebræ, rupture or stretching of ligaments, hæmorrhagic extravasations, etc., which produce decided and more or less permanent objective symptoms. Even in the case of the existence of the latter, the physician should be on his guard, and satisfy himself that the paralysis or muscular atrophy was not produced by some other cause.

In his (Dr. Watson's) experience, railroad accidents more frequently cause injuries of the viscera than of the nervous system. The lungs are lacerated, or contain hæmorrhagic infarctions; there are lacerations of the liver or spleen, ruptures of blood-vessels in the bladder or other viscus.

DR. PENROSE, of Philadelphia, communicated to the association a paper on the same subject, which was read by the secretary. The views advanced were similar in kind to those above presented. He thinks that spinal concussion analogous to cerebral concussion is almost unknown. He protests against the robbery of cities and corporations by claimants who have nothing but pain or other subjective symptoms to substantiate their claims.

DR. W. H. PANCOAST had a word to say in defence of the general public who have certain rights of protection which they may justly demand of railroad officials. He did not believe that there had been as much shamming as had been represented by previous speakers. He had some faith in spinal concussion as the older authorities have taught it, where long disability without paralysis or atrophy follows an injury, and thinks that the victims of accidents should be recompensed for even a temporary shock and consequent sufferings.

DR. SMITH, in closing, said that the railroad companies are always ready to settle just claims. Witness the Lehigh valley awards. It is the exaggerated and fraudulent claims that they contest.

DR. M H. RICHARDSON, of Boston, read a paper on

THE SURGERY OF THE PERIPHERAL NERVES.

It was a very reliable presentation of the results in the Massachusetts General Hospital of neurectomy and nerve stretching for neuralgia and painful muscular spasm. Exsection has been oftenest performed in the inferior dental nerve, which is comparatively easy of access. In 1876 the first operation for avulsion and destruction of the whole nerve was performed, and this operation has been several times repeated since then. The buccal nerve has in several instances been divided where it comes out over the buccinator, and the inferior maxillary nerve has been cut down upon at its point of emergence from the foramen ovale, and a portion exsected. This is a rare and difficult operation. Nerve stretching has been performed mainly for neuralgias of the sciatic. The operation has been five times performed in the Massachusetts General Hospital; the results have not been favorable. He does not think that traction stretches the spinal cord. In neuralgias of the inferior dental nerve, stretching has done good in a few cases. Muscular spasm has in some instances been relieved by nerve stretching, *e.g.*, stretching of the facial for tic douleureux, stretching of the supraorbital nerve for spasm of the brow muscles, of the spinal accessory for spasm of the sterno-mastoid and trapezius.

There have been seven cases of nerve suture; these pertained to the median, ulnar, and musculospiral nerves, and this operation was attended with marked though very gradual return of power and function. The nerve ends must be freshened, brought loosely together, and a few fine catgut or silk sutures put in.

DR. W. H. PANCOAST spoke of neurectomy of the fifth nerve, as performed by his father, the late Dr. Joseph Pancoast. The latter was the first to reach the inferior maxillary nerve trunk by sawing through the condyle, and to cut it close to the foramen ovale. He (the speaker) had made several exsections of the sciatic and crural nerves in obstinate neuralgias.

DR. GORDON, of Portland, said that he had several times stretched both sciatic nerves, then the anterior crural, for the *douleurs fulgurants* of locomotor ataxia; the operation was attended with great relief.

SECTION ON OBSTETRICS.

First Day.

President, DR. W. H. WATHEN, of Louisville, Ky.; secretary, DR. A. B. CARPENTER, of Cleveland, Ohio.

CHRONIC INVERSIONS OF THE UTERUS

was the subject of a paper by DR. HENRY O. MARCY, of Boston, who presented numerous illustrations of this trouble in crayon drawings, and made a very interesting talk and demonstration. He sketched somewhat briefly the history of chronic inversion of the uterus and its etiology, and then discussed more fully the pathological changes which ensue. He somewhat critically reviewed the experience of Dr. Thomas and his followers in first performing laparotomy in order to dilate the cervical constriction and thus aid the reposition of the organ. He had studied the matter faithfully and at last came to the conclusion to pass long ligatures of coarse silk deeply through the cervical tissues which he determined were possessed of ample resisting power. The doctor presented an instrument, simple, yet possessed of sufficient power for the work. It has at the distal end a cup-shaped extremity for the reception of the fundus. The deep cervical ligatures, four in number, are attached to a movable sleeve adjusted upon the shaft of the instru-

ment. By means of a screw in the handle pressure is brought to bear upon a concealed spring and the force applied is at once determined upon a graduated scale, showing the amount of pressure. Dr. Marcy reported one case which came under his care during the past year. Dr. Clark, of Cambridge, Mass., and Dr. Cleveland, of New York, spoke in terms highly complimentary of the instrument.

DR. E. E. MONTGOMERY, of Philadelphia, read a paper on

THE INDICATIONS FOR AND LIMITATIONS OF THE OPERATION FOR THE REMOVAL OF THE UTERINE APPENDAGES.

He concluded that the operation should be promptly performed in every case in which it is evident that relief cannot be otherwise obtained. It should be considered a *dernier ressort*, and its consideration should be dismissed in every case capable of restoration to health by other plans of treatment.

DR. JOSEPH PRICE, of Philadelphia, read a paper on

A SERIES OF FIVE HUNDRED CASES OF CONFINEMENT IN A MATERNITY,

in which he gave the minutiæ of the treatment in a maternity hospital in Philadelphia with which he is connected. The treatment was after the highest and most approved method of cleanliness. He said the talk a few years ago was to abolish the lying-in hospitals on account of their terrible mortality. The tables are now turned, and the greater mortality is in the private practice. He wished to invite a discussion which would lead to more refinement in the technique of the treatment of labor.

DR. THOMAS OPIE, of Baltimore, had visited the maternity spoken of and found it unique. He had great hopes for the future in this line.

DR. HIRST, of Philadelphia, considered the plumbing of great importance. In an infirmary where he practised he had the closets put in towers where the ventilation was excellent, and had noted within twenty-four hours a fall of temperature. He had found the mortality to be very great in tenement houses where the plumbing was at fault.

DR. W. T. LUSK, of New York, thought that the practitioner should hold himself responsible for the plumbing of the house in which he delivered patients.

DR. HENRY D. FREY, of Washington, D. C., read a paper on

THE APPLICATION OF THE FORCEPS TO TRANSVERSE AND OBLIQUE POSITIONS OF THE HEAD; DESCRIPTION OF A NEW FORCEPS.

He had sent circular letters addressed to the teachers of obstetrics in the United States asking their practice in these conditions and the kinds of instruments they used. He gave their replies in a tabulated form. He thought the obstetrician should not content himself with one form of instrument, but be expert with several, so as to be able to use them as occasion demands.

DR. WM. S. STEWART, of Philadelphia, read a paper on

WHEN SHOULD THE OBSTETRIC FORCEPS BE USED, AND WHAT FORM OF INSTRUMENT IS REQUIRED?

They should never be used to save time or to satisfy nervous women or fidgety nurses. We should use the form of forceps best fitted to the particular case. He presented a pair of his make which he had used in a number of cases with good success. In these either blade can be introduced first, the child is not disfigured, and they do not slip.

DR. JOSEPH TABER JOHNSON, of Washington, M. C., thought that women in childbirth were entitled to all the skill of the obstetrician, and spoke in high praise of the forceps in labor.

DR. THEOPHILUS PARVIN, of Philadelphia, regarded the instrument exhibited as the revival of an old instrument, which will also become an old instrument and be revived by some one else. He thought it dangerous, that it would crush the child's head. It was an ingenious, complicated instrument, but we want simplicity. The power is too far remote from the resistance for the nearer you can get a horse to the load he pulls the better he will pull.

DR. JOSEPH PRICE, of Philadelphia, looked upon the forceps of Dr. Stewart as dangerous instruments.

DR. THOMAS OPIE, of Baltimore, read a paper on

THE KINSHIP OF OBSTETRICS AND GYNECOLOGY.

He reviewed the history of obstetrics from the earliest times and always found it closely allied to the diseases of women. He found obstetrics and gynecology bound together with hooks, forceps, and specula of steel. A few years ago the opinion was that lying-in-hospitals should be abolished. Now they challenge private practitioners with their results. Gynecology has grown out of obstetrics, an obstetric development, they are separated but not divorced; they interdigitate. The gynecologist should know obstetrics and the obstetrician should be a good gynecologist. The very nature of the gynecologist insists that he should be first an obstetrician. To know the abnormal he should first know the normal. United they stand like Siamese twins. To separate them would inflict irreparable injury. The obstetrician has long cried honestly against feticide, that old commandment, "thou shalt not kill," and the gynecologist against Onanism, the limitation of families and sterility. He considered the thought of breaking up this long-standing alliance between obstetrics and gynecology, which had taken the form of a resolution before the general sessions, sinful.

DR. H. R. STORER, of Newport, read a paper on

BENJAMIN RUSH AS AN OBSTETRICIAN.

In studying medical numismatics he had been struck with the importance of the work of Benjamin Rush in the department of obstetrics. Fifty years ago the idea of the induction of anæsthesia in obstetrics was an American idea in the mind of Rush, and he, after observing a painless delivery while the mother was in an epileptic fit, and another while the mother was intoxicated, prophesied the finding of a drug which would relieve the pains of childbirth. The writer brought this sub-

ject up before this section because he thought Rush a man who deserved well of the section in obstetrics, especially as an effort was now being made to raise him a monument. On resolution the paper was referred to the general sessions when the subject came up.

Dr. W. W. Potter, of Buffalo, N. Y., read a paper on

BORACIC ACID IN GYNECIC PRACTICE.

The doctor was first brought to the use of boracic acid by the fact that iodoform in him always caused a very troublesome dermatitis. He found boracic acid valuable when the medication was required to remain longer in the vagina than it was possible for tampons to remain on account of the decomposition. He then described minutely his method of applying the remedy, which consisted of an injection, a drying of the vagina, the application of the boracic acid with alternating layers of cotton. He, in some cases, allowed this dressing to remain a week, and thought once a week often enough for these applications. He has had good results with boracic acid after plastic operations. In these cases he leaves a rope of borated cotton hanging from the os over the perineum.

He considered boracic acid a remedy of great value in sterility due to acrid secretion which destroys the fecundating power of the sperm. It is one of the best powders to render operative wounds in the genital tract aseptic. Boracic acid is suited to many gynecic uses where an antiseptic is required.

It can claim superiority over the vaginal tampon by reason of odorless, colorless, non-irritant chemical properties; these admitting of its frequent liberal and prolonged treatment.

THE PATHOLOGY OF ECTOPIC PREGNANCY AND PELVIC HÆMATOCELE.

The president's address was delivered by Dr. W. H. Wathen, of Louisville, Kentucky. He considered that the ovum was never impregnated in the uterine cavity, and thought that the conjugation of the male and female elements must take place before or just after the ovum enters the tube. Ectopic pregnancy is always primarily tubal, with possible exception of ovarian pregnancy. Abdominal pregnancy cannot occur except as a result of primary or secondary rupture, and if the villous or placental attachments are destroyed the ovum immediately dies, because it cannot form secondary attachments to other structures. If in rupture into the peritoneal cavity the ovum retains villous or placental attachments it may be possible under certain conditions for the pregnancy to continue, though not probable. If the amnion is ruptured in the early months the embryo or fœtus will die. So-called interstitial pregnancy does not always, though usually, rupture into the peritoneal cavity. If we define pelvic hæmatocele as an encysted or confined tumor formed of blood, then intra-peritoneal hæmatocele is not possible. Then followed an extensive argument upholding these propositions advanced concerning ectopic pregnancy.

The intimate relations existing between pelvic hæmatocele and ectopic pregnancy was his reason for considering these two subjects together in his address. Nearly every author who has written on this teaches that blood may accumulate in the peritoneal cavity and become rapidly encysted and fixed by the effusion of a layer of lymph exudations. The author did not adhere to this belief.

Dr. Wm. H. Taylor, of Cincinnati, read

THE REPORT OF A CASE OF ECTOPIC GESTATION SUCCESSFULLY TREATED BY GALVANISM.

The great practical importance of extra-uterine gestation and the prominence it now holds as a topic of discussion he thought justified his contribution. The diagnosis being difficult the first essential interest centres about this point. The doctor then gave a concise review of the latest published utterances on the subject of diagnosis and symptomatology. His case was then reported.

Dr. Georges Apostoli, of Paris, France, read a paper on

SALPINGO-OVARITIS.

(To be continued.)

THE MAINE MEDICAL ASSOCIATION.

THE THIRTY-SEVENTH ANNUAL MEETING, HELD AT PORTLAND, JUNE 11TH, 12TH, AND 13TH, 1889.

First Day — Tuesday, June 11th — Morning Session.

The association was called to order by the President, Prof. S. H. Weeks, M.D., of Portland, at 10 A.M., in the Common Council Chamber, City Building.

Prayer was offered by the Rev. Wm. H. Fenn.

The report of the treasurer, Dr. A. S. Thayer, of Portland, showed a balance on hand of $632.39, less by over three hundred dollars than that of last year, a decrease due to litigation over the Medical Registration Bill.

Dr. D. N. Skinner, of Auburn, read a paper on

GLAUCOMA,

urging the necessity of early diagnosis, so as to secure the benefit of prompt operative interference by iridectomy or sclerotomy; much stress was laid upon differential diagnosis, for the reason that remedies usually relied upon in treatment of diseases likely to be confounded with glaucoma were, if used in this affection, positively harmful. As between eserine and pilocarpine, the preference was given the former, the latter frequently causing ciliary spasm.

Dr. Jason Walker, of Minot, read a paper upon

EPIDEMIC JAUNDICE IN CHILDREN,

the cause being obscure and not traceable to sanitary defects or the ingestion of irritating substances. Curiously enough, each case developed after an interval of about two weeks from the appearance of the case preceding.

The question was raised whether catarrhal jaundice might not be of microbic origin; no explanation was suggested why in the epidemics cited by the author as occurring within his observation the disease was confined to children and youth.

Dr. A. G. Young, secretary of the Maine State Board of Health, read an interesting statistical paper upon

THE PREVAILING DISEASES OF THE YEAR.

First calling attention to the refusal of the last legislature to provide any means for an adequate collection of vital statistics, as requested by the State Board of Health, the speaker gave some facts with reference to frequency and relative prevalence of disease. Pulmonary tuberculosis headed the list, followed in order by diphtheria, scarlet fever, typhoid fever, and small-pox; measles and cerebro-spinal meningitis were represented by a few cases. Small-pox occurred at Cumberland Mills primarily, secondarily at Brownfield and Deering, *presumably* from handling infected rags of domestic or English origin. Fourteen cases occurred, with two deaths; all but five of one hundred and six exposed in the rag room had been vaccinated. Of the five unprotected three were attacked by variola and furnished the two deaths.

This paper also noted the prevalence of jaundice in epidemic form in eleven towns, but not specially confined to children except as noted by the preceding speaker.

A resolution was offered by Dr. Young, and unanimously adopted by the association, offering its assistance to the census office in securing trustworthy vital statistics of this State for the next census.

DR. J. O. WEBSTER, of Augusta, also a member of the State Board of Health, read a paper on

THE SANITARY DUTY OF PHYSICIANS IN DISEASES OF THE COMMUNITY.

The speaker said the title of his paper meant "the duty of physicians in preventing the spread of disease through the community." Upon the insight, the experience, the good-will, and the sense of duty of the physician first called for the treatment of a given case of contagious disease principally depends whether the first case of such disease comes seasonably, late, or not at all to the knowledge of the sanitary authorities. Epidemics at the present day are largely due to disregard of the first principle of preventive medicine herein indicated.

Merely satisfying legal requirements by reporting such cases is of little avail or credit to him who does so, if measures are neglected looking to the discovery of the source, the etiological conditions, and the various preventive measures proper in each case.

Lack of intelligent co-operation on the part of the medical profession is almost fatal to the efficiency of a local health board.

Another element difficult to manage is the resistance opposed to sanitary placards and restrictive measures by business interests.

The problem to be successfully solved by sanitary authorities is how to secure the greatest possible prevention of commonly dangerous diseases of the people.

Afternoon Session.

The afternoon session opened at 3 o'clock with the introduction of DR. P. H. Ingalls, of Hartford, Connecticut, and Dr. A. S. C. Millett, East Bridgewater, Massachusetts, as delegates from their respective State societies; followed by the president's address, delivered by DR. S. H. WEEKS, professor of surgery in the Medical School of Maine.

He reviewed the present law regulating the supply of material for the study of practical anatomy and showed it to be essentially prohibitory from its unreasonable requirements; he urged an attempt to secure its amendment by reducing the time of keeping bodies subject to the wishes of friends from three days to five days.

The decision of the Supreme Court adverse to the position of the association in relation to the late Registration Act was announced, and the association advised to formally undertake the preparation of a new bill for presentation to the next legislature.

The removal of the Medical School of Maine to Portland was insisted upon as necessary to its continued vitality and usefulness.

DR. S. C. GORDON, of Portland, read a paper on

PREGNANCY AND OPERATIVE SURGERY: THEIR MUTUAL RELATIONS,

arguing that general surgical operations, and even those of a special nature, upon the uterus and appendages are permissible, provided hæmorrhage into the cavity of the uterus be prevented.

Operations remote from the pregnant uterus, however trivial, should be done under anæsthesia by ether. No operation should be made upon or near the uterus, unless imperatively demanded by the condition of the patient, until after confinement; but experience and accidental operations have demonstrated that operative interference may be safely made.

The speaker said that, while there was much less to fear now from minor operations than before antiseptic measures were inaugurated, there still remains the danger of septicæmia, which is always a powerful cause of abortion or premature labor.

DR. JAS. A. SPALDING, of Portland, read a paper upon

MERCURY CONSIDERED AS AN AGENT IN GENERAL THERAPEUTICS.

Evening Session.

DR. I. T. DANA, of Portland, read a paper on

APOPLECTIFORM SEIZURES, DISCUSSING FOUR TYPES, THE EMBOLIC, THE HÆMORRHAGIC, THE CONGESTIVE, AND THE URÆMIC.

Apart from some interesting remarks by Dr. H. G. Beyer, U.S.N., upon cerebral localization, the discussion brought out nothing but conventional methods of observation and treatment.

Second Day — June 12th — Morning Session.

The association met at 10 o'clock. A telegram of congratulation was received from the Oregon State Medical Society, in session at Portland, Oregon, and was answered by a like message.

DR. R. D. BIBBER, of Bath, reported a case of obscure disease of the brain, which post-mortem examination showed to have been extensive both in cortex and medulla, but attended by few definite symptoms.

DR. G. A. PHILLIPS, of Ellsworth, read a paper upon

CASES OF WILD-PARSNIP POISONING.

Botanically and in physiological action this plant

resembles the water-hemlock. It is the *pastinaca sativa* of Gray.

The poison takes effect in direct ratio to the rapidity of the digestive powers in children, about two hours after the ingestion of the root. The symptoms are flushing of the face, mental dulness, followed soon by twitching of the extremities and severe convulsions, with coma, pupils widely dilated, respiration shallow, pulse weak, rapid, and thready, tongue dry and swollen. Treatment was by opium and prolonged etherization, after emetics and enemas.

Death occurs in cases not promptly relieved. Strong infusion of the root injected under the skin of a cat had no other effect than to widely dilate the pupil.

Dr. Phillips was requested by the association to continue his study of the plant and report at the next annual session.

Dr. E. T. Nealey, of Bangor, read a paper on

THE RELATION OF MICRO-ORGANISMS TO INJURIES AND SURGICAL DISEASES.

He confined himself principally to the question, "Do bacteria, pathogenic or non-pathogenic, exist in the human healthy body?" and argued in the affirmative.

Dr. E. E. Holt, of Portland, read a paper on

TREATMENT OF ULCERATION OF THE CORNEA,

laying special stress upon the necessity of careful differential diagnosis, and its importance in determining the selection of proper remedies.

Dr. Abiel Libby, of Richmond, reported a case of puerperal convulsions relieved by venesection. The discussion showed that the general preference in treatment was for morphia and anæsthesia, placing little dependence upon chloral and bromides.

Second Day — Afternoon.

Officers were elected as follows: —

President, Dr. B. F. Sturgis, Auburn; first vice-president, Dr. A. L. Hersey, Oxford; second vice-president, Dr. R. D. Bibber, Bath; corresponding secretary, Dr. J. L. M. Willis, Elliot; the treasurer, Dr. A. S. Thayer, and permanent secretary, Dr. Chas. D. Smith, hold over, being elected for a term of years.

Dr. H. F. Twitchell, of Freeport, read a paper upon

PLEURITIC EFFUSIONS,

supplemented by another by Dr. J. A. Donovan, of Lewiston, on

DOUBLE TYPHOID PNEUMONIA FOLLOWED BY EMPYEMA.

Opinion embodied in the discussion seemed to be in favor of aspiration of effusions as soon as it was evident that absorption was not progressing. Dr. S. C. Gordon, of Portland, emphasized the advisability of evacuating purulent cavities through an opening secured by resection of a portion of one or more ribs, in preference to puncture through an intercostal space. He mentioned a modification of the usual method of closing abscess cavities, as devised by him, which consisted in dividing the chest wall at the junction of the ribs with their cartilages, allowing the chest to completely flatten.

Dr. E. H. Hill, of Lewiston, read a paper urging the establishment of a general hospital at Lewiston or Auburn, to meet the demand created by a large manufacturing population.

Dr. A. K. P. Meserve, of Portland, presented the necrologist's report, containing obituary notices of Dr. J. Q. A. Hawes, Hallowell; J. S. Cushing, Skowhegan; Galen J. Tribon, Steuben; Rufus K. Cushing, Bangor; Geo. H. Chadwick, Portland.

The evening session was devoted wholly to the

ANNUAL ORATION,

by Dr. F. E. Hitchcock, of Rockland, the subject being

EUTHANASIA.

He considered in detail natural anæsthesia, as exemplified by asphyxia, coma, syncope, and similar conditions; artificial anæsthesia by drugs; euthanasia in its relations to the death penalty; and the limitations of the physician's right to contribute to painless death.

Following the oration, the members, ladies, and invited guests were entertained at an elaborate reception given by the retiring president, Dr. Weeks, at his residence on Congress street.

Thursday, June 13th.

The closing session opened at 10 o'clock A.M. and was occupied with committee reports, appointment of standing committees, and listening to the final report of the board of censors. Dr. D. A. Robinson, of Bangor, was selected as orator for the session of 1890.

Delegates were appointed to the American Medical Association, the State medical societies of the New England States, New York, and New Brunswick, and visitors to the Medical School of Maine, the Portland School for Medical Instruction, and the Maine Insane Hospital.

Following the report of the special committee on the president's address,

Committees were appointed to secure an amendment to the existing law governing anatomical study, and to draft and present to the next legislature a new bill providing for medical registration.

The following resolutions were given a unanimous passage: Resolved: That the cause of medical education at the present day *demands* that medical schools shall offer facilities for clinical as well as didactic instruction.

Resolved: That the vitality and future prosperity of the Maine Medical School depends upon its removal to Portland, where the clinical instruction available at the hospitals and dispensary can be made a part of the education of its graduates.

The association then adjourned, to meet in Portland on the second Tuesday in June, 1890.

NEW YORK ACADEMY OF MEDICINE.

Meeting held June 20, 1889.

REPORT ON THE POLLUTION OF THE CROTON WATER-SHED.

Dr. John C. Peters, chairman of a committee consisting of Dr. A. Jacobi and S. Baruch in addition to himself, appointed at a previous meeting in regard to nuisances along the Croton water-shed, made his first report. Having referred to the

recent thorough investigation of the pollutions and liabilities to pollution of the water-supply by the State Board of Health, he said that the next thing to do was to secure the removal of such sources of contamination and the protection of the water from contamination in the future. Having been informed that under the existing laws the responsibility of the matter lay with the Department of Public Works, the committee wrote to the commissioner, Mr. Gilroy, stating that the report of Sanitary Inspector Lucas of the New York city board of health, in 1884, showed that 1874 more or less preventable nuisances had been allowed to arise, and that the recent report of the State Board of Health showed that in 1888 these had increased to 2843. These consisted largely of out-door privies and indoor water-closets which emptied directly into the city's drinking water, of the sewage of whole villages and towns, and of large hotels and boarding-houses, and of the drainage from many barnyards, stables, pig-stys, and factories, and eighty-three cemeteries. As many new summer resorts were being developed on almost all the lakes and many of the streams going to make up the Croton river, and as thriving villages were arising almost everywhere along the three railroads traversing the region, it was to be supposed that these nuisances would increase still more rapidly in the near future. Concluding with the statement that previous departments of public works seem to have been entirely unconscious of their responsibilities and duties in these matters, the letter urged the commissioner to take prompt and decisive action in regard to them.

Mr. Gilroy replied that he would do all in his power to abate the nuisances, but that his department must act under the supervision of the State Board of Health; whereupon the committee wrote to Dr. Balch, secretary of the latter, who stated that Mr. Gilroy was mistaken, and that under the laws the Department of Public Works alone had the authority to remove the pollutions. Dr. Peters concluded his report by stating that all that the committee had therefore succeeded in accomplishing thus far was to find out just where the responsibility in the matter lay, and that their efforts in the future would be directed towards stirring up the Department of Public Works to do its duty.

—The students of the ambulance corps of the New Orleans Charity Hospital have made their appearance in uniforms. The outfit consists of a navy blue suit, square-cut sack coat with brass buttons, and a white cap.

—It is said that milk producers in New York State think they see a small measure of promised relief from the present depression of prices due to over-supply, in the development of the sugar-of-milk (*saccharum lactis*) manufacturing industry. Formerly consumers of the article in this country have depended entirely upon importations from Switzerland and Bavaria, and it is only lately, and in view of the increasing demand, that an attempt has been made to supply the market with a home-made product.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 4, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of The Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money order, draft, or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE MORTALITY IN THE CITY OF NEW YORK FOR 1888.

A PRELIMINARY report in relation to the mortality of the city for the year 1888 has just been presented to the board of health by Dr. Roger S. Tracy, the assistant sanitary superintendent, and the deductions made in it are somewhat remarkable. The sanitary police took a census of the tenement-house population during the year, which includes all the houses that are more or less constantly under the supervision of the board of health, but not the better class of apartment houses. The entire population included in this census was 1,093,701 persons, among whom there were 24,842 deaths, while the total number of deaths in the city was 40,175. The highest death-rate, 26.60 per thousand of the population, is in the district south of 14th street and west of Broadway; the next highest, 23.52, is in the district west of Fifth avenue and between 14th and 59th street, in which are situated a large proportion of the residences of the wealthiest citizens; and the third highest in the district east of Broadway and south of 14th street, the most densely populated part of the city, and containing almost exclusively a tenement-house population.

The general tenement death-rate was 22.71, while the general death-rate of the city in 1888 was 26.33, and this fact would seem to indicate that the population of the city has been under-estimated, and the quoted death-rate too high, or that all the deaths belonging in tenement-houses had not been credited to them, or else that the death-rate is actually lower for the tenement-house population than for the rest of the city; which would certainly seem most extraordinary. It might be that deaths that should have been credited to the tenement-houses have not been so credited; but of the total number of deaths in institutions, 7774, the former place of residence

of the individuals was ascertained in 3444, and these deaths have all been credited to the houses in which they had lived. In all the districts the death-rate of persons five years of age and over as a rule decreases as the number of tenants increases, while the death-rate of children under five years of age increases up to a certain point, diminishing when there are more than eighty tenants to a house. The general death-rate is highest in houses containing from sixty to eighty tenants, and this is caused by the higher death-rate among the children, which reaches in these houses 114.04 per 1000 living.

The results of the investigation are summed up by Dr. Tracy as follows: The death-rate in tenement houses is less than the general death-rate of the city. The death-rate in the large tenement houses is less than in the smaller ones. While diarrhœal diseases and diphtheria show a greater death-rate in the larger houses, phthisis and pneumonia show comparatively little difference, that difference, however, being in favor of the larger houses. The greatest general death-rate among persons over five years of age, the next to the highest death-rate from diarrhœal diseases and pneumonia, and markedly the highest from phthisis, are in the district south of 14th street and west of Broadway. The excessive mortality in this part of the city is probably connected with the great number of old houses and the dampness of the soil. These results are much at variance with what was expected. It seems to be sufficiently established that people do not live under such extremely bad sanitary conditions in the tenements as they have been supposed to.

THE AMERICAN MEDICAL ASSOCIATION'S ANNUAL MEETING.

None can more appreciate the interest of the medical meetings lately held in Newport than the country physician who looks back through a score or more of years in the dim vista of the past, to the time when he was a medical student, and realizes the immense progress which has been made in all departments of medicine and surgery, and the imperfect manner in which he has kept up with all this progress. In the various sections he saw, among the men who were to take part in the proceedings, physicians who are representatives of the profession of to-day, at whose feet he is content to sit in the humble attitude of a learner. His only difficulty was to know how best to improve the opportunity, for the programmes of all the sections were sufficiently tempting, and every one felt the embarrassment of choice where much was so good. If one chose to attend the Section on Surgery, one found no cause for regret. In fact, the programme under this head this year was remarkably good, and a wide range of subjects was discussed in a manner often singularly clear and thorough; the country physician who had his eyes and ears open could not have failed to learn more about spinal surgery and concussion, herniotomy, lithotomy and lithotrity, aseptic dressings, etc., than he could have acquired in months of desultory reading in his own office.

As is usually the case, special interest centred in the Surgical Section; speakers and auditors were enthusiastic; the discussions far exceeded the time allotted to them, and extra sessions in the evening had to be appointed to finish the work left undone in the afternoon. Valuable papers were crowded out. Members present on the evening of the 27th will not soon forget the papers on hernia, and the earnest discussion which followed; the meeting was prolonged to midnight.

The programme of the Section of the Practice of Medicine was also an uncommonly good one. Much might be said in commendation of the papers read; they were generally of an eminently practical character. Such speakers as Delafield, Osler, Pepper, Tyson, Whittaker, Edes, Vaughan, Davis, it is a great privilege to hear, even if for this purpose the country physician must travel from Texas or from Oregon.

In the Section of Obstetrics and Gynæcology fifty-five papers were announced. Of course many of these were read only by title. Leading specialists from all parts of the Union were present; several of the speakers were distinguished foreigners. If our medical Rip Van Winkle, after his long sleep of fifty years, had appeared on the scene, he would have listened with astonishment as he heard the laparotomies and hysterectomies and ovariotomies described as affairs of everyday gynæcological surgery.

The general practitioner who comes all the way from California or Washington Territory to attend these meetings will miss a great deal if he altogether skips the Section on Pædiatrics, as well as that on Dermatology and Syphilography. His first case of cholera infantum after his return home may die if he has failed to hear and profit by such a paper as that of Dr. Greenley, "On the Management of Infants during the first year," or the equally valuable paper of Dr. Brush, "On Cow's Milk for Infant Food." With regard to dermatology, the ordinary physician knows too little, and needs to be switched out of the common routine of arsenical medication and saline purgation by some such wide-awake, enthusiastic cutaneous specialists as were present at Newport. Members who listened to the address of Bulkley on the first day, entitled "Recent

Advances in the Treatment of Diseases of the Skin," were heard to speak of it in terms of great satisfaction.

Other sections, as that of State Medicine, Dietetics, Laryngology, and Otology, attracted their coteries of attentive listeners, and some very good papers were read in these sections. Country practitioners have found it highly desirable to know something about all these topics, and it were greatly to be wished that the meetings might be so arranged that, like the general sessions, only one thing would be going on at a time. Then members could step from practice to surgery, and from surgery to gynæcology, etc. But alas! such a scheme is probably impracticable for life is too short, and busy physicians cannot be induced to spend more than three or four days at a great medical meeting. Fortunately, the medical journals are able by their corps of reporters to give to their readers the best things that were said.

The addresses before the general sessions were as usual: Dr. Dawson, President, spoke of the physician of to-day, the physician of the future, medical journals, laboratory work, etc. The address on general medicine by Dr. William Pepper consisted principally of thoughts suggested by the life of Benjamin Rush. Dr. P. S. Connor gave the address on general surgery on the third day. It contrasted the surgery of the present with that of the past. Dr. W. H. Welch delivered a very admirable address in the Section on State Medicine.

In many respects the selection of Newport for the place of meeting was a felicitous one, and members found an agreeable diversion from the task of listening to so many papers in the beautiful scenery of the locality, and in the numerous excursions and other entertainments which had been provided for them. The air was cool and bracing, the weather fine. But few complaints were heard from visitors who had failed to obtain good accommodations. Some, it is true, were obliged to go to private houses to obtain lodging places. The places chosen for the general meetings and sectional meetings — Music Hall, Bellevue avenue, and adjoining rooms in the same building, and in the Newport Casino, were all that could have been desired.

The representation from the Western States was smaller than usual. Had there been a large attendance from that part of the country, in addition to those who did go, the need of more ample hotel accommodations would have made itself uncomfortably felt. The opinion was somewhat generally expressed that large centres of population and large centres of railway lines offer distinct and undeniable advantages for such meetings, — although, in the selection of Nashville for the next place of meeting, this opinion was not allowed great weight.

MEDICAL NOTES.

— We are assured by Americans living in Venice, Italy, that there would be an excellent opening there for a competent young American practitioner of medicine.

— Press despatches from Ottawa say: "A few weeks ago it was reported to the department of agriculture here, which is charged with the administration of health matters in Canada, that there were cases of leprosy prevalent in Cape Breton Island, N. S. Dr. Smith, medical attendant at the leprosy lazaretto at Tracadiz, N. B., was instructed to make a personal investigation into the matter.

This report, which has just reached the department, shows that there are three distinct cases of leprosy on the island, two women and one man. The disease has made terrible ravages on the latter, and Dr. Smith reports him to be a most repulsive looking object.

BOSTON AND NEW ENGLAND.

— A very pleasant complimentary dinner was given at Young's Hotel, Boston, on the 20th inst. at which some thirty members of the Cambridge Medical Society were present. The occasion was the celebration of the fiftieth year of continuous practice by Dr. W. W. Wellington, of Cambridge. Dr. J. L. Hildreth, president of the Cambridge Medical Society, conducted the after-dinner exercises, which were of an informal character. Dr. Wellington gave many reminiscences of his many years of practice, and he was followed by Drs. Morrill Wyman, A. C. Webber, and H. O. Marcy.

— At a meeting of the students of the Medical School of Maine, held in Brunswick, June 24, the following resolutions were formally adopted by the students: —

Whereas we, the students of the Medical School of Maine, unanimously believe that the benefits of the school are marred by the lack of clinical advantages, and for this reason many of the students are accustomed to leave the school at the end of the first or second year to finish their course in schools possessing greater clinical facilities; and

Whereas the city of Portland presents by far the best advantages of any locality in the State, both clinical and in other respects, —

Resolved, That we unanimously second the resolutions relative to the removal of the Maine Medical School adopted by the Maine Medical Association at their last session.

— Governor Ames has appointed the following members of the Metropolitan Drainage and Sewerage Commission: John Quincy Adams, of Quincy;

Asa French, of Braintree; and Hosea Kingman, of Bridgewater. All are members of the legal profession.

NEW YORK.

— At the last meeting of the New York Academy of Medicine, Dr. Walter Mendelson introduced a series of resolutions protesting against the appointment to the position of president of the board of health of an individual entirely without the sanitary knowledge requisite for a proper performance of the duties of the post, and urging the mayor of the city to reconsider his actions in the matter, and appoint some person properly qualified. On motion, the resolutions were referred to the council of the academy.

— The disinfecting corps of the New York city board of health made its first visit to Long Island City on June 25th, and many houses where there were or had been cases of diphtheria were disinfected. The mayor of Long Island City has also issued an appeal to the citizens to do all in their power to prevent the further spread of the disease.

— The board of health has called the attention of the Department of Public Works to obstructions in the sewer, and the bad drainage on the river front contiguous to Bellevue Hospital.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 22, 1889.

Deaths reported 2341; under five years of age 1266; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 659, consumption 277, acute lung diseases 168, diarrhœal diseases 439, diphtheria and croup 92, typhoid fever 40, scarlet fever 30, whooping-cough 20, measles 19, malarial fever 10, erysipelas 5. From scarlet fever, Philadelphia 10, New York 8, Brooklyn 7, Baltimore and Washington 2 each, Lawrence 1. From whooping-cough, Brooklyn and Boston 2 each, New York 4, Philadelphia and Washington 1 each, Gloucester 2. From measles, Philadelphia 6, New York 5, Boston 2, Baltimore, Washington, Nashville, Cambridge, New Bedford, and Haverhill 1 each. From malarial fever, New York 5, Philadelphia and Brooklyn 2 each, Baltimore 1. From erysipelas, New York and Philadelphia 2 each, Brooklyn 1. From cerebro-spinal meningitis, New York, Baltimore, and Worcester 1 each.

In the 28 greater towns of England and Wales, with an estimated population of 9,555,406, for the week ending June 8th, the death-rate was 17.7. Deaths reported 3244; infants under one year 769; acute diseases of the respiratory organs (London) 295, measles 152, whooping-cough 98, diphtheria 49, diarrhœa 67, scarlet fever 41, fever 23.

The death-rates ranged from 10.1 in Leicester to 36.1 in Preston; Birmingham 13.4; Halifax 27.0; Hull 22.1; Leeds 18.2, Liverpool 18.1; London 15.7; Manchester 30.2; Newcastle-on-Tyne 22.7; Sheffield 19.5; Sunderland 21.4.

In Edinburgh 15.1; Glasgow 23.5; Dublin 21.3.

The meteorological record for the week ending June 1, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps: —

Week end'g Saturday, June 1, 1889.	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.*			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 22, 1889, TO JUNE 28, 1889.

By direction of the Secretary of War the extension of leave of absence on surgeon's certificate of disability granted Major WILLIAM H. FORWOOD, Surgeon, in S. O. No. 118, May 22, 1889, from this office, is further extended four months on surgeon's certificate of disability. Par. 14, S. O. 142, A. G. O., Washington, June 20, 1889.

CORSON, J. K., Major, Surgeon, U. S. Army, granted leave of absence for one month, with permission to apply for an extension of one month. Par. 2, S. O. 65, Headquarters Department of the Columbia.

By direction of the Secretary of War Major EZRA WOODRUFF, Surgeon, is relieved from temporary duty at Fort Monroe, Va., and will report in person to the Commanding Officer at Fort Hamilton, N. Y., for duty at that station. Par. 5, S. O. 146, A. G. O., June 25, 1889.

By direction of the Secretary of War the extension of leave of absence granted Captain WALTER W. R. FISHER, Assistant Surgeon, in S. O. 41, June 12, 1889, Divis. of the Pacific, is still further extended fifteen days. Par. 8, S. O. 146, A. G. O., Washington, June 25, 1889.

HOFF, JOHN VAN R., Captain, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Reno, Ind. Ter., and ordered to Fort Riley, Kansas. By par. 6, S. O. 145, Washington, D. C., June 24, 1889.

BACHE, DALLAS, Major, Surgeon, U. S. Army, is relieved from duty at Fort Riley, Kan., and ordered to report to Commanding General, Department of the Platte, for duty as Medical Director of that department. Par. 6, S. O. 145, A. G. O., Washington, D. C., June 24, 1889.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JUNE 29, 1889.

SIEGFRIED, C. A., Surgeon, detached from the U. S. S. "Quinnebaug" and wait orders.

CURTIS, L. W., Passed Assistant Surgeon, detached from the U. S. S. "Quinnebaug" and wait orders.

SMITH, GEORGE T., Assistant Surgeon, ordered to the Army and Navy Hospital, Hot Springs, Ark.

APPOINTMENT.

DR. HENRY C. COE has been appointed Professor of Gynecology at the New York Polyclinic, to fill the vacancy caused by the death of Dr. James B. Hunter.

SOCIETY NOTICE.

AMERICAN PUBLIC HEALTH ASSOCIATION.

PRELIMINARY ANNOUNCEMENT. — The seventeenth annual meeting of the American Public Health Association will be held at Brooklyn, N. Y., October 22, 23, 24, 25, 1889.

The Executive Committee have selected the following topics for consideration at said meeting: I. The causes and prevention of infant mortality. II. Railway Sanitation: (*a*) Heating and ventilation of railway passenger coaches; (*b*) water-supply, water-closets, etc.; (*c*) carrying passengers infected with communicable diseases. III. Steamship sanitation. IV. Methods of scientific cooking. V. Yellow fever; (*a*) The unprotected avenues through which yellow fever is liable to be brought into the United States; (*b*) the sanitary requirements necessary to render a city or town proof against an epidemic of yellow fever; (*c*) the course to be taken by local health authorities upon the outbreak of yellow fever. VI. The prevention and restriction of tuberculosis in man. VII. Methods of prevention of diphtheria, with results of such methods. VIII. How far should health authorities be permitted to apply known preventive measures for the control of diphtheria. IX. Compulsory vaccination. X. Sanitation of asylums, prisons, jails, and other eleemosynary institutions.

Papers upon miscellaneous sanitary subjects not included in the above list will be received by the Executive Committee, subject to the requirements of the By-Laws. Preference will be given, however, to papers upon the subjects selected by the committee in making up the daily programme of the meeting.

IRVING A. WATSON, *Secretary*.

CASE OF POISONING BY WATER GAS, WITH NEW METHOD OF TREATMENT; RECOVERY.

BY D. A. CLEAVELAND, M.D., MIDDLETOWN, CONN.

The subject of the use of water gas as an illuminating agent has been attracting much notice for several years past, and within the past six years the interest in the subject has greatly increased, owing to the persistent efforts which have been made by interested parties to introduce plants for its manufacture in those States whose citizens have been protected from its direful effects by statute laws.

This has been notably the case in Massachusetts, the only State, with one exception, in the country whose policy it has been to protect its citizens from dangerous adulterations of most of the articles in daily use, and which are among the necessaries of life.

Consonant with this policy, as is perhaps well known to most of your readers, a law was enacted by the Massachusetts legislature in 1880, prohibiting the sale of illuminating gas containing more than 10 per cent. of carbonic oxide.

Probably to this statute law, and the discussion growing out of an attempt to secure its repeal, we are largely indebted for the valuable investigations which have been prosecuted in relation to the poisonous nature of water gas.

For, under the stimulus of a threatening evil, with characteristic energy and thoroughness, commissioners were appointed in Massachusetts, who, acting in unison with the State Board of Health, deduced from scientific observation and actual experiments upon living animals facts which have clearly proved the dangerous nature of the gas, and largely enriched the literature of this subject.

It has been left to the citizens of those States unprotected by any legal provision against the sale of this dangerous compound to learn by experience the fatal effects following its use, either by the careless and forgetful or those bent upon suicide.

During the past six years, while acting in the capacity of medical examiner for this city, I have been called in a number of instances, both ante-mortem and post-mortem, to persons who were poisoned by the inhalation of water gas.

The symptoms presented by persons affected by the inhalation of this gas do not differ widely from those seen in persons who are deeply unconscious from the effects of other lethal poisons, except that the coma is more persistent and profound, and continues for several hours, with no marked change until near the end of life; then a sudden change in the respiration, a rapid failure of the heart's action, then a few forcible respiratory movements and the breathing suddenly ceases and the patient is dead. A brief inquiry in relation to the nature of water gas is perhaps proper, even though it weary some in the profession who are already familiar with the subject, as it will lead to a better understanding of its peculiar toxic influence.

It would not be in accord with my purpose, which is to make this article as brief as possible consistent with the importance of the subject, that I should enter into a discussion of the nature of all the chemical elements of which this gas is composed. Neither is it necessary, as the whole subject has been ably treated by several learned gentlemen, and its literature is full and comprehensive.

I shall therefore confine myself to the especial toxic element, carbonic oxide.

As long ago as 1875 the mayor of Boston appointed Charles F. Choate, Esq., and John T. Osgood, Esq., of Boston, and Prof. Edward S. Wood, of Cambridge, commissioners to inquire into the subject of gas manufacture.

In their report made the following year, speaking of water gas they say: "In reference to the poisonous nature of this gas, the constituent carbonic oxide is one of the most active poisons, producing when inhaled speedy death. . . . It forms a compound with the red coloring matter of the blood, which is more stable than that formed by carbonic anhydride, and it cannot be readily decomposed by oxygen."

In 1885 Dr. Samuel W. Abbott, secretary of the Massachusetts Board of Health, in his report for that year, shows that Bernard and Hoppe-Seyler demonstrate that "carbonic oxide displaces the oxygen from the blood, and enters into combination with the red coloring matter in such a manner as to render it incapable of absorbing more oxygen."

Profs William M. Sedgwick and William Ripley Nichols, of the Massachusetts Institute of Technology, made a careful study of the relative poisonous effects of coal and water gas, under the direction of the Massachusetts Board of Health in 1885, and verified the statements contained in their report by actual experiments upon living animals, both in this city and at Athol, Mass.

I will quote a single paragraph from that report. Speaking of carbonic oxide they say: "It exerts, for example, a direct action upon the living blood-cells of the animal body, depriving them of the power of performing their normal functions, and if present in sufficient quantity speedily undermines the functions of the whole body.

Dr. E. A. Down, one of the assistant physicians to the Connecticut Hospital for the Insane, contributed a paper to the Connecticut Medical Society, which will appear in the Transactions of the society for the present year, in which, besides referring to the case which is herein reported, he gives an able exposé of the whole subject relating to the toxicology and general characteristics of water gas.

An analysis of the two gases most used for illuminating purposes shows that coal gas contains 5.53 and water gas 27.46 per cent. of carbonic oxide.

This is the average obtained from several analyses of gases from different localities. The gas supplied to this city averages 30.33 of carbonic oxide.

This carbonic oxide is the especial toxic element with which we have to do when called to a case of poisoning by either coal or water gas; but as coal gas contains less than 6 per cent. of carbonic oxide we ordinarily find but little difficulty in resuscitating persons under its influence, providing they still breathe. For the changes in the red corpuscles of the blood are so slight, that a free inhalation of

oxygen, with the employment of heart stimulants, will generally restore the patients.

This is not the case, however, with those deeply affected with the inhalation of water gas, as will presently be shown.

Considering, then, the deadly nature of water gas, and the perils attending its use, either as an illuminating agent or for fuel purposes, and in view of the fact that all the methods hitherto employed to resuscitate persons who have become deeply affected by its inhalation have been, so far as I have been able to learn, entirely unavailing, all the patients having died, it has occurred to me that the presentation of the following typical case may not be without interest and perhaps profit to the medical profession, especially in those localities where water gas is in use.

At 12.30 P.M., on the 27th of last March, I received the following telephone message from Dr. Olmstead, superintendent of the Connecticut Hospital for the Insane, located about a mile out of the city: —

"We have two cases of poisoning by water gas. One we think will recover, but the other is considered moribund. As you are interested in such cases, and will have to see the patient post-mortem, perhaps you would like to see her ante-mortem."

I hurriedly responded to the courteous invitation, and on my arrival at the hospital learned that Mary Fleming and Mary Doughty, two laundry women in the hospital, were discovered at 7 A. M., six hours previously, unconscious from having inhaled water gas that escaped into their room while they were probably asleep.

The Doughty woman was lying near a partially opened window and in a direct line between the window and a ventilator in the door which opened into the corridor. She was not so deeply affected as the other woman, and slowly regained consciousness.

The Fleming woman, who was found lying upon her bed in a corner of the room remote from the windows, was the one referred to as being moribund.

There were in attendance upon this woman Drs. Noble, Fisher, and Down, all of whom had worked diligently in their endeavors to save her life, from the time she was discovered until I arrived, a period of about six hours.

Artificial respiration had been kept up almost continuously, with the patient constantly exposed to a current of fresh air. Besides this there had been about twenty feet of pure oxygen administered by inhalation.

Hypodermics of ammonia, atropine, and other heart stimulants had been freely employed, and all this without the least appreciable effect.

The patient was in a profound coma. The countenance livid, the extremities cold, and in fact but little if any warmth of any part of the body that was exposed. The coma was completely anæsthetic, and there was an entire suspension of all sensory functions. The pulse would beat eight or ten times with a fair fullness and then run down to a mere flutter, and for a moment be entirely lost at the wrist. Then again there would be a few quite forcible beats, followed by the rapid diminution and entire suspension.

The respiration corresponded in character, if not in rhythm, with the pulse, there being a few forcible respiratory movements, succeeded by a rapid diminution in their depth until they would cease altogether. Then a sudden forcible inspiration would follow, to be succeeded by the rapid decline and suspension.

There were facial spasms of the right side and large dilatation of the right pupil.

Mucus was collecting in the trachea, giving rise to what is known as the death-rattle.

Hurriedly taking in the situation, and with a brief consultation with the physicians present, who agreed with me that if any further measures were to be tried there was no time to be lost, and in consonance with views expressed at a consultation with these physicians over a previous case, I proposed that I be permitted to transfuse her at once, which proposition met with ready approval.

There being no transfusion instruments at hand, and as time was precious, I called for a clean Davidson's syringe, an aspirator needle, a file, a whetstone, some warm fresh milk, all of which were promptly furnished. Cutting off the point of the needle and smoothing the end with the whetstone, and having the needle attached to the nozzle end of the syringe, the necessary apparatus was complete. Then applying a bandage above the right elbow I opened the median cephalic vein and drew about ten ounces of blood.

As the vein was opened there was a spurt of blood that flew two or three feet, then dwindled down to a mere dripping. Then it would well up again for a moment and then recede to a mere dripping, thus corresponding with the force of the pulse.

The blood was allowed to flow until the weakness in the heart-beat gave warning that the limit of safety had been reached. The bandage was then removed and placed below the elbow to prevent any further flow of blood.

Then pressing the little and ring fingers of the left hand above the orifice in the vein to prevent the entrance of air, leaving the other fingers and thumb to assist in the introduction of the needle, the needle was introduced about three-fourths of an inch, and about ten ounces of milk very slowly injected into the vein.

The needle was then withdrawn and a bandage applied to the arm.

The first indication of returning sensibility was noticed when the needle was pushed a little too high in the vein when nearly through with the injection, and its end impinged against the coats of the vein at the point of union of the cephalic and median cephalic. This sensibility was manifested by a motion, as if caused by a twinge of pain.

Two hours after the operation there was a marked improvement in the appearance of the patient, and four and a half hours after the operation she swallowed and retained stimulants, which she had not done before since she was discovered at 7 A.M., twelve hours previously.

There was on the day following quite a marked redness in the track of the vein above which the opening was made, but it soon subsided on the application of warm lead and opium wash. Excepting this and a very small abscess near the point of

incision, which Dr. Down opened as soon as it was in suitable condition, and which did not gather again, there was no further trouble with the arm.

There was also a large and troublesome abscess formed at the angle of the jaw, which was evidently caused by the cold wind blowing on that point for a period of six or seven hours, but under the judicious management of Dr. Down, with the advice of Drs. Noble and Fisher, there were no unfavorable results from it. Twenty-five days after the operation she was able to sit up, and continued to improve until she perfectly recovered, and has remained well up to the present time.

I have entered more fully into the minute detail of this operation than would be warranted in the description of an operation of more common occurrence. I have done it, however, not to enlighten the experienced practitioner, who may have performed it several times, but for the benefit of any practitioner who may, for the first time, be called to a case when hurried transfusion may be deemed advisable.

The literature of transfusion is very incomplete in many of the text-books, and there is a paucity of detail in regard to it. And in some of the books the directions are confusing, having evidently been written by persons who have never operated nor seen it done.

I trust, however, that any practitioner may learn from the description here given how, by the observance of a few simple rules, the operation can be easily and safely done. And upon an observance of these rules may depend the facility and rapidity with which it can be done; and cases requiring transfusion are generally those demanding prompt and speedy action.

For convenience I will condense a few important points into one or two short paragraphs: If the operator be right-handed let him select the right arm of the patient, and take his position upon the outside. His position will enable him to use the left hand for controlling and compressing the vein, and the right for bleeding and introducing the needle.

Select the median cephalic vein, as it lies nearest the operator and its direction is favorable for introducing the needle without the end impinging against the coats of the vein. After bleeding, compress the vein above the opening with the little and ring fingers of the left hand, and carefully introduce the needle.

Before releasing the pressure above the orifice, press the ball of the left fore-finger flatly over the needle at the point of entrance to prevent the entrance of air. Inject the liquid very slowly, to avoid the fatal complication of paralysis of an already enfeebled heart from too sudden venous plethora.

The above directions, of course, do not apply to immediate or vein to vein transfusion.

The description of the instruments used on this occasion is given to show that in extreme emergencies we can sometimes improvise instruments that will do as good service with as favorable results as could be obtained with all the surgical appliances of an elaborately furnished hospital.

The rationale of the anomalous method of treatment employed in this case can be stated in few words: —

By the presence of carbonic oxide in the blood the integrity of the red corpuscles was destroyed, and they could no longer absorb oxygen, consequently artificial respiration, and even the inhalation of pure oxygen, were of no benefit.

These facts well established, it seemed desirable to first reduce the amount of carbonic oxide in the blood, and, second, dilute the remaining portion and at the same time maintain a suitable degree of venous tension. The first object was obtained by bleeding, and the second by transfusion of a suitable liquid.

As there was no time to lose in drawing blood from a bystander, and going through the process of defibrinating it, and the instruments at hand were not suitable for vein to vein transfusion, the only choice was milk. And were I to perform the operation again, I should use milk in preference to other liquids, as it contains many elements of blood, is about the same density, and is always readily obtained.

TWO CASES OF BENIGN PAPILLOMATOUS BLADDER GROWTHS,

SUCCESSFULLY REMOVED BY THE PERINEAL ROUTE.[1]

BY FRANCIS S. WATSON, M.D.

APART from the value that individual operations in this class of cases afford in the still comparatively early period of their surgical history, in contributing to the sum of our experience in the matter, these two cases present some points of clinical interest which have seemed to me noteworthy.

CASE I. is that of a gentleman aged thirty-eight, who consulted me in April, 1888, for the symptom of hæmaturia, which he had had for three years previously. It was of the type usually associated with intra-vesical growths, and the diagnosis was at once made positive by the microscopic examination of the urine, which contained bits of a papillomatous tumor. April 23rd, 1888, I removed by the perineal route a large, thickly pedunculated, papillomatous growth by a pair of strong forceps, afterward scraping the site it had occupied with a curette. The patient went home on the sixteenth day, the wound healed and the urine free entirely from blood. In the following year he gained about thirty pounds in weight, and had no urinary symptoms whatever, until April 23rd, 1889, exactly one year from the date of the operation. He then had a profuse hæmorrhage from the bladder, and continued to bleed more or less until after the second operation, May 15th, 1889.

On that date the deep urethra was again opened as before. The outer sphincter of the bladder, formed by the compressor urethræ muscle, was apparently as intact as though it had never been subjected to the violence that was done on the first occasion. The site of the original growth, which was just above the right lobe of the prostate, was wholly free from any recurrence.

Just behind the symphysis pubis, on the anterior surface of the bladder, was a sessile papilloma,

[1] Reported at the annual meeting of the Association of American Genito-urinary Surgeons, Newport, May 22, 1889.

occupying an area about as large over as a silver quarter of a dollar. Above this, toward the fundus, were three small growths, with long pedicles. One of these and the sessile growth were removed by a curette. The other two pedunculated bodies were taken away with a wire snare, and their bases curetted.

Recovery from this second operation was also rapid. A large drainage-tube was retained in the bladder, through the perineal wound, for twenty-four hours, then removed. Hæmorrhage was free for the first day, then diminished, and ceased wholly on the third day. The perineal wound closed on the tenth day, and the patient was also up and about on the same day, and went home on the thirteenth day, the urine clear. There was scarcely any pain following the operation, and but very slight bladder irritability during the first few days of convalescence. The temperature rose to 100° F. on the evening of the day of the operation and was thereafter normal.

The points which interested me in the case are: 1. The thorough restoration of the urinary sphincters after the first perineal operation. 2. The absence of recurrence of the disease in its original site; and this especially in view of the fact that the destruction of its attachment to the bladder by the curette had not been extensive at the time of the first operation, which shows that the bladder bases of benign tumors do not require such radical destruction always, to prevent recurrence, as has been supposed by some surgeons. Lastly, this case gave an opportunity to estimate in a single instance the rate of growth that may take place in such papillomata, and how extensive it may be before hæmorrhage is noticed, for it is certain that at the completion of the original operation the bladder was free from any growth sufficiently developed to be felt by the finger.

CASE 2. A young man of twenty-one years of age. Partial and persisting incontinence of urine from birth. Six years ago, at a single urination only, the urine contained a large quantity of blood. This was never noticed again until April of this year, when hæmaturia again occurred and continued in every urination until the day of operation, May 18th, in greater or less quantities. For two weeks the urine was examined daily: no characteristic bits of a new growth were discovered. The sediment, besides the blood, always contained numbers of polymorphous epithelial cells of great variety, having large nuclei, and bodies which resembled so closely hyaline casts of the renal tubules as to be very difficult to distinguish from them. The physical examination was wholly negative, and there was no other indication of renal disease.

On May 18th Nitze's cystoscope was introduced into the bladder, and through it I thought that three delicate villi of a bladder growth could be seen, but before obtaining a good view of them the electric lamp burned out. Digital exploration of the bladder through the perineum was then undertaken. The sphincter vesicæ was scarcely detectable, and the finger entered the bladder in consequence with unusual readiness. The bladder surface was unusually smooth, and its muscular tissue unusually thin. No growth was felt after careful search. A curette was then passed over the bladder surface, and encountered resistance on its posterior face. On removing the instrument a bit of a papillomatous growth was seen upon its edge; guided by this knowledge the finger then felt a soft, delicate sessile growth, covering an area about the size of a silver half-dollar between and above the ureteral orifices. This surface was freely curetted.

Bleeding was slight. A drainage-tube was retained in the bladder through the perineal wound for twenty-four hours, then removed. All bleeding ceased at the end of the second day following the operation; on the fourth day the patient had a chill and rise of temperature to 102° F., after which convalescence has progressed uninterruptedly thus far, though the urine contains a considerable quantity of pus still. The perineal wound closed on the fifteenth day.

In this second case I wish to call attention to — 1. The failure of development in the sphincter vesicæ muscle, and the dependence upon this condition of the patient's enuresis, and also the accompanying lack of muscular development in the bladder wall itself and the thin, smooth mucous membrane of the bladder associated with it. 2. The doubt as to diagnosis which arose from the failure to find characteristic bits of a bladder growth in the microscopic examinations of the urine, but especially from the presence of the hyaline bodies that so closely resembled casts of the renal tubules. To be sure I did not find a single example in which these bodies had two well-defined, rounded ends; but then, it sometimes happens that hyaline casts are broken in such a way as not to show perfect forms. Dr. W. W. Gannett, who reported growth to be a very delicate papilloma, thought it probable that the hyaline forms were portions of the blood-vessel stems of some of the finer papillæ forming the growth, which had undergone hyaline degeneration, and in the entire absence of all evidence of renal disease and the disappearance of these bodies from the urine after the operation, this seems the most natural explanation. I have dwelt somewhat at length upon this detail of the case for the sake of explaining a possible source of confusion in the diagnosis.

A very natural question may occur here. Why delay to make the diagnosis by the microscope when we have so rapid and satisfactory a means of diagnosis in the electric cystoscope of Nitze? In reply to which I would say that I always try to make the diagnosis of a bladder growth at first without the cystoscope, for the reason that, so far as I have observed, the introduction of this or any instrument into such bladders is peculiarly liable to excite cystitis, which is adverse to favorable result. (Therefore, also, I do not follow the advice sometimes given to wash out the bladder or to try to detach bits of the growth by instrumental manipulation for diagnostic purposes.) It seems better to reserve cystoscopic examination until just before operation, in order to demonstrate the presence or absence of a growth in a doubtful case, or to determine its site, size, etc., in one in which its existence has already been established, as a guide to the choice of operation, being always prepared to enter the bladder either from above or below according to circumstances. Used in this way, the cystoscope is, I believe, capable of giving valuable infor-

mation. But it should also be borne in mind that it may mislead, as I have known it to do now in two examples and in the hands of surgeons thoroughly conversant with its use. In one instance a prostatic hypertrophy was taken for a villous tumor; in another a tumor was said to exist, but could not be discovered when sought by operation.

It is unusual, moreover, to have to wait long before finding in the urine of these cases unquestionable proofs of the tumor's existence if it be present.

Supplementary note, three weeks after operation.

Since writing the above report another interesting observation has been made in this case, namely, the discovery that the bladder contains *eight ounces* of residual urine, due to the congenitally defective muscular development of the organ, and present in spite of the patent condition of the vesical orifice that is caused by the lack of development of the sphincter vesicæ muscle. This failure of the bladder to empty itself becomes now an important factor in the case, from the fact of the large quantity of pus which the urine contains, and which the bladder cannot rid itself of by natural efforts; and more especially is this important because of a very great sensitiveness of the anterior urethra, which makes it almost impossible to wash out the bladder through instruments passed through the urethra after closure of the perineal wound.

FOUR CASES OF PHTHISIS TREATED BY INHALATIONS OF HOT AIR.

BY GEORGE G. SEARS, M.D.

Since Koch's discovery of the tubercle bacillus the history of what is new in the treatment of phthisis has been largely that of the rise and fall of various methods for the disinfection of the respiratory tract. Each new method proposed for accomplishing this end has promised brilliant results in the hands of its originators, unfortunately unconfirmed by a fuller experience. This constant succession of disappointments may have had much to do with the indifference at first shown by the profession toward the treatment by inhalations of hot air which has been recommended within the past year by Halter, Weigert, and Krull, though without doubt it has been further handicapped by the questionable proceeding of Weigert in patenting his apparatus and in publishing a popular treatise on "Consumption and its Cure," savoring somewhat of quackery. Recently, however, more attention has been turned to it, and it is with the endeavor to form a basis for the intelligent estimation of its value that the following cases are reported. The number was necessarily small, owing to the length of time required for carrying out its details. All the patients were inmates of the House of the Good Samaritan, in the services of Drs. F. C. Shattuck and C. M. Jones, to whom I am indebted for their kindness in placing them at my disposal and for many valuable suggestions. They had been kept under observation from two weeks to three months, that the general tendency of the disease might become known and the improvement which so frequently follows admission to a hospital from better diet and general hygienic conditions might not be falsely ascribed to the method of treatment.

At the time these observations were begun Weigert's apparatus was not yet on the market nor even patented, and the descriptions which had appeared in the medical journals seemed so complicated that the following simple apparatus, suggested by Mr. G. L. Kingsley, of the Harvard Medical School, was devised. It consisted of a cone-shaped spiral of copper tubing, the base being about six inches in diameter. The lower end extended outward far enough to obtain a supply of air uncontaminated by the gas stove which furnished the heat, while the upper end projected at right angles to the axis of the cone, and was fitted with a mouthpiece. A second piece of tubing was inserted into this to hold the thermometer, and the cone itself was covered with a sheet-iron shield. A somewhat rude but efficient mouth-piece was made from a piece of asbestos-board covered by rubber tubing. The temperature of the inspired air, at first 160° C., was soon raised to 200°, and even to 220°, while the length of the sittings was gradually increased from a half-hour morning and evening to one hour. Beyond this limit it was rarely possible to go, owing to the exhaustion of the patients, who were encouraged to take as long and deep breaths as possible. Except the salivation and soreness of the mouth noted in Case I. the only disagreeable effect complained of was double vision, which lasted but for a short time after each sitting, and was present only for the first few days. The routine hospital treatment was continued in each case, and consisted in the administration of tonics, creasote, and a full diet.

Case I. Woman, thirty-eight years old. Beginning phthisis, scanty expectoration containing a few bacilli. Jan. 17th, 1889. Treatment began, inhalations of a half-hour in duration being given twice daily with a temperature of 160° C. They excited an almost constant short, hacking cough and a profuse flow of saliva.

Jan. 22nd. Inhalations have been increased to forty-five minutes A.M., and forty minutes P.M., while the temperature has been raised to 210° C. Salivation is so profuse while she is at the apparatus as to seriously interfere with its use. She complains that her mouth is very sore.

Jan. 23rd. Mouth so sore that inhalations had to be omitted. During the week she has lost three pounds in weight, and the temperature, which had previously kept within normal limits, varied but little either morning or afternoon from 100° F. A day or two later it again dropped to normal.

Case II. Woman, æt. twenty-three, without hereditary taint. Advanced phthisis, with signs of a cavity in left apex, and slight crackle in the right above and below the clavicle and in the supraspinous fossa. Cough slight, most troublesome at night, with scanty expectoration containing a few bacilli. Has never been confined to bed and has never had hæmoptysis. Was placed under treatment Jan. 17.

Jan. 24th. She reported herself as feeling much encouraged; there had been no cough for several nights, her dyspnœa had decreased so that she could now go up stairs without special discomfort. Sleep and appetite were improved.

Mar. 1st. There is still less dyspnœa and her

appetite remains fair, but the improvement in cough was but temporary.

Mar. 17th. Is in bed. Cough has increased and the expectoration contains considerable blood, from half an ounce to an ounce in the twenty-four hours. During the following week the hæmoptysis continued, the inhalations being omitted. On attempting to resume them the effort proved so exhausting that after a few days they were discontinued. The patient's general condition was then less satisfactory than before treatment was begun, and the physical signs showed an extension of the process on the right side, the respiration being bronchial as low as the third rib, while an explosion of fine râles occurred after cough over the upper half of the chest in front.

CASE III. Woman, æt. twenty-two, with negative family history. Advanced phthisis involving nearly the whole of the left lung, with signs of an incipient process at the left apex. Cough not very troublesome, expectoration moderate in amount, containing numerous bacilli, slight sweating at night, considerable dyspnœa on exertion. No hæmoptysis.

Jan. 23rd. Inhalations begun. Mar. 9th. Steady improvement during the past six weeks. Dyspnœa is less, and cough and expectoration have decreased. She has gained four pounds in weight, and her strength and color have both improved. The pulmonary signs, however, have remained practically unchanged.

Mar. 29th. Has lost two pounds during the past two weeks and cough and expectoration have slightly increased, but she reports herself as feeling better and says she can now go up stairs without trouble. Inhalations omitted.

April 3rd. Death from hæmorrhage.

CASE IV. Woman, æt. twenty-two, with tubercular family history. Well-marked signs of phthisical process in right lung, slight cough, with but little expectoration, containing a few bacilli. No hæmoptysis. Sits up all day.

Mar. 1st. Treatment begun. Mar. 26th. Considerable blood in expectoration during the past few days, during which the inhalations were omitted. April 15th. Has become so thoroughly alarmed by the death of the other patient, which she attributes to the hot air, that it was no longer possible to continue. During these six weeks her general condition has remained about the same. There was neither increase nor loss in weight, and beyond a slight gain in her ability to sleep there was no improvement to record, while the cough and expectoration had both increased.

To briefly summarize the results obtained: In one case the inhalations were omitted after a week, owing to salivation and soreness of the mouth, with a loss to the patient of three pounds in weight. This loss simply emphasized the general tenor of the case, as it was afterwards partly regained and was fairly attributable to mental disturbance, as she expressed great anxiety at the possible effects of such unusual therapeutics.

In one case (II.) temporary improvement was quite marked, but at the time the treatment was discontinued there had been a further advance of the disease, and for the first time in the history of her illness hæmoptysis occurred.

In one case (III.) there was fairly steady improvement in the general condition of the patient, but without a corresponding improvement in the physical signs. She had, however, already begun to improve during the two weeks she was under observation, before the inhalations were begun, and a part at least of the gain must be attributed to hospital care. Five days after they were omitted death resulted from hæmorrhage.

In one case (IV.) the condition of the patient remained unchanged, but during this period blood was present in the sputum for the first time.

Excepting Case I., where a rise in temperature level of a degree and a half occurred, no permanent change was noticed in its course. The other three cases had previously shown an afternoon rise to 100° or 101°, and this continued unabated. The immediate effect was an elevation of from 1° to 3° F., which always subsides in the course of an hour or two. No special alteration was noted in either pulse or respirations. The increase in expectoration which is said to occur during the first few days seemed in these cases to be due, in part at least, to the stimulation of the salivary glands. Considering the relative frequency of hæmoptysis in phthisis, it is an open question how far one is justified in attributing its regular occurrence in these cases to the form of treatment. It is impossible that air should reach the lungs with a temperature even approaching 200° C., as a part of the heat is lost by radiation between the thermometer and the lips, and much more in the mouth and upper air-passages from the absorption of moisture, still it must retain a considerable portion on reaching the pulmonary alveoli, as Weigert has found that the temperature of the expired air is 113° F., while according to Kohlschütter it may considerably exceed this (140° C.). In other words, a hot poultice has been applied to the lungs, an active hyperæmia induced, and with it increased danger of the giving way of the wall of some vessel weakened by ulceration or aneurismal dilatation. This danger would, moreover, be still further increased by the rarefaction of the air inspired, which, at 50° C., has been calculated by Halter to be of the same density as at a mountain elevation of 1530 metres, while the patient himself remains exposed to the ordinary atmospheric pressure. The sputum was examined on several occasions for bacilli by Dr. E. M. Greene, in the hope of detecting a constant diminution in their number, but the result in every instance was negative, with the possible exception of Case III.; but as they had never been numerous the slight diminution in this instance may have been simply accidental. It is hard to believe that bacilli situated in the lung substance, and protected by a layer of moist tissue, can be at all affected by air at any temperature which can be inhaled. Whatever germicidal action it possesses must be exerted after they have reached the surface, where it may be of value, partly in shutting up one avenue of further infection by making any secretions carried by the respiratory current into healthy portions of the lungs less noxious, but more perhaps in limiting the danger of contagion by rendering the bacilli inert before they are expectorated. It is comparable to

the oiling of the body of a scarlatinal patient: it produces little effect upon him, but furnishes a certain amount of protection to others.

Conclusions drawn from so small a number of cases are apt to be untrustworthy, but in these instances the following summary seems justifiable:

1. Cases so treated differed but little in their course from those treated by the older methods. Whatever gain was noticed seemed more justly attributed to the expansion of the lungs from forced inspirations than to any effect of the hot air *per se*.

2. Little influence can be expected from it upon the development of the bacilli. Any germicidal action it may have is largely exerted in sterilizing the bronchial secretion, and is to be looked upon rather as a prophylactic measure against the spread of the disease than as curative in any particular case.

3. While it is not proven that the occurrence of hæmorrhage in these cases was not all dependent upon the form of treatment, theoretical considerations make it probable that it increases the tendency thereto and suggest caution in its use.

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.[1]

BY E. H. BRADFORD, M.D., AND E. G. BRACKETT, M.D.

INTERNAL DERANGEMENT OF THE KNEE.

John Croft[6] reports removal of a large portion of the semilunar cartilage of the knee for persistent internal derangement. It was attached by the anterior and posterior extremities, but displaced upward into the intercondyloid notch. About three-fifths was excised. The patient made a good recovery with a strong and useful joint.

He considers that the semilunar cartilages may be dislocated from their anterior or posterior attachments, or both; that rupture from the posterior attachment must be very rare, if it ever occurs; that when the circumferential relations are ruptured the cartilage tends to displace into the intercondyloid notch, and that when the anterior attachments are torn through the cartilage tends to displace inwards and backwards.

Annandale (page 164) gives the following conclusions from his five cases.

(1) That the internal semilunar cartilage is the one most frequently displaced. Of the five cases only one involved the external cartilage.

(2) That three different forms of displacement occur: —

(*a*) Separation of the anterior and posterior and lateral attachments, the cartilage being displaced backward and outward (three cases).

(*b*) Separation of anterior and lateral attachments, the cartilage being folded upon itself (one case).

(*c*) Separation of anterior and lateral attachments, the inner edge of the cartilage being turned over and lying in the intercondyloid notch (one case).

(3) The joint and limb should be kept perfectly at rest after the operation, for at least six weeks, and then, when the wound is soundly healed, careful movements of the joint and general massage of the limb should be employed.

(4) That the result in all my five cases has been excellent.

Allingham[7] also reports a case of removal of a portion of the semilunar cartilage, after which the patient made a complete recovery.

R. J. Goodin reports a case of dislocation of external fibro-cartilage, in which it was torn away and rested vertically in the intercondyloid fossa. This differs somewhat from the ordinary cases, in which the deformity is reported as on the inner side.

DOUBLE HIP-DISEASE.

Ridlon[8] gives the following from the analysis of his cases.

The disease seldom begins in both hip-joints at the same time, and the second joint may become diseased while the patient is resting in bed under treatment for the first joint.

The joint first affected is often the last to recover.

The duration of the disease in the hips is usually somewhat less than that of the average case of hip-disease, while the duration in the second is usually much less than that of the first.

The influence of derivative effect upon the first joint is not borne out by these (his cases), as the second has got well before the first. The beneficial effect is more to be attributed to the rest necessitated by the involvement of the second joint.

HYSTERICAL HIP.

Glorieux[9] reports a case of hysterical hip occurring in an otherwise healthy man, and is, according to the author, the second reported as observed in man, the other having been described by Charcot. On the maternal side there was an alcoholic history, and one sister was affected with some neurosis. The case presented the usual picture of ordinary hip-disease, but there was never any fever or disturbance of general nutrition, and contraction entirely disappeared under chloroform. There was general pain over the leg, and disturbance of sensation, which corresponded, not to the distribution of nerves, but to the zones of central innervation which are frequently seen in hysterical affections. In spite of long duration of the disease, there was no vaso-motor or trophic disturbance. The differentiation of this condition from one of monoplegia from central organic lesion is well considered in the article.

Bilhaut[10] describes a condition seen twice by him, and which he designates as "coxalgie simulée." The cause of the disturbance is a lack of symmetrical development of tho two legs, this difference being more than could be called physiological. The symptoms were slight, but those of early hip-disease, and were noticed as soon as the child began to walk. They consisted of a favoring of the leg, turning out of the toe, and complaint of fatigue after even slight exertion. In standing the weight was borne alternately on the two feet. Examination of the joint was negative; no hysteria. Nutrition of the two limbs equal,

except that the affected leg seemed a little less firm. There was, however, a difference in length of 1½ cm. in favor of the unaffected side. By use of an additional sole the symptoms entirely disappeared. No cause for the asymmetry was found; but the importance of recognizing such a condition, associated with the symptoms of a serious affection, is evident.

THERAPEUTICS IN JOINT DISEASE.

Lovett[11] has used with marked success the salicylate of soda in chronic joint disease attended with acute symptoms, and has found it valuable in the following conditions: (1.) When night cries are present. (2.) When the diseased joint is very painful and sensitive to jar. (3.) When vomiting and general discomfort are associated with an increase in the local disease. It was used only "as an adjunct to proper mechanical treatment," and in doses up to the physiological effect or until the symptoms were relieved. In this way it has proved a valuable means for the quick relief of the acute symptoms.

SENILE COXITES.

H. L. Taylor[12] has tried effects of rest with extension. Traumatism seems to have exciting or aggravating effect on many of those cases.

After a month or six weeks of rest with traction, the muscles about the hip seem softer, and the position and mobility improved. The patients are then given a Dow's and allowed moderate exercise with the benefit of fresh air. Two cases reported in which benefit was derived.

A CASE OF RACHITIS ADOLESCENTIUM.

C. B. Keetley[13] reports a case of rachitic curve of upper part of femur, simulating a condition of dislocation. Duration about eight years (then fourteen years). Operated by wedge-shaped osteotomy, resulting in cure. In this case there was also a scoliosis.

LATERAL CURVATURE.

Mr. Bernard Roth[14] calls attention to the inaccurate and unsatisfactory ways of recording lateral curvature, and describes the method followed by him for some time. He considers the conflicting statements in regard to the cure of curves of various degrees of severity to be due to the lack of systematic classification, and suggests the following: (1.) Those without any osseous deformity, postural stage. (2.) Those with osseous deformity, osseous stage — which may be divided into (*a*) slight, (*b*) moderate, (*c*) severe or extreme. His method of recording, although it may not have received the attention of writers, is not new to many orthopedists and depends upon the rotation of the ribs. The patient is made to stand in front of the surgeon and bend forward, holding the knees stiff. A tracing is then taken with a pliable metal tape, transversely across the back, at a level with the lower angle of the scapulæ. This is then transferred to paper. A similar tracing may be taken over the erector spinæ.

[13] Illus. Med. News, 1888-9, i. 7.
[14] Brit. Med. Jour., Oct. 27, 1888, 927.

In treatment[15] he advocates re-education of muscular sense and methodical exercises of the muscles to enable them to maintain this improved position without effort.

Fischer[16] recommends daily exercises for three quarters of an hour each day.

First. The patient lays both forearms on a cushion placed upon a stool so that the back is nearly horizontal, a band is placed around the trunk and a weight hung upon that. These weights are increased up to 80 kilogrammes and more; the weight must be continued as long as the patient can endure it. The first treatment for several minutes, afterwards for one-fourth of an hour.

Second. The patient stoops so that the back is at right angles with the legs and leans against a horizontal bar padded at both ends so as to press upon the shoulder and pelvis; a strap passed around the trunk passes over the bar and the weight hung upon this exerts a lateral pressure.

These weights can be adjusted according to the situation of the curve. No cases are reported used with this apparatus.

Schwartz[17] has devised a new method of suspension, which enables the correction of the scoliotic trunk. After the correction has taken place a plaster jacket is put on in a corrected position.

The arrangement is a complicated one, but it is said to accomplish the purpose intended. A full description of the appliance is hardly possible here, but the readers are referred to the article itself.

ISCHIAS SCOLIOTICA.

Schudel, in the *Archiv für klinische Chirurgie*, 38 Band, 8 Heft, 1888, describes what he calls ischias scoliotica, a curvature of the lower portion of the spine, which is accompanied with symptoms of sciatica. The deformity is due to the relative inability of the muscles for an active contraction on account of the disease of the sensitive nerve in the muscles. The lumbar nerves are the ones affected with neuralgia.

SHOULDER STRAPS, ETC.

Roth[18] urges strongly against their use at all. As said by John Shaw,— that the muscles whose place they take atrophy from disuse, while the opponents, being developed, increase the deformity as soon as the straps are removed, by faulty antagonism. As a result which often happens when straps are pulled too tightly, the shoulders are held far backward, thus producing marked lumbar lordosis.

THE FORCIBLE AND IMMEDIATE REDUCTION OF OLD SUBLUXATION OF THE TIBIA.

Bradford[19] describes a new instrument for the reduction of subluxation of the tibia. From experiments on cadavers it was found that the tibia could be pushed forward fully an inch. The first resistance encountered is the posterior crucial ligament, which becomes tense after the application of considerable force. The posterior ligament can be

[19] Tr. Internat. Cong., 1887, ix. iii. 646.

stretched, and affords but little resistance in a normal joint.

In cases of severe tubercular osteitis, with recovery with fibrous ankylosis, and subluxation of the tibia, forcible straightening of the limb does not reduce the subluxation. The tibia does not slide forward, but is held back by either the hamstrings or contracted capsule.

The apparatus is shaped much like a tuning fork, with the ends of the two prongs so curved, that when the leg is placed between the forks the curve of each corresponds to the bend at the knee. A broad band passes behind the leg at the upper part of the tibia, provided with a screw by which this may be forced forward. Pads are placed over the patella by which counter pressure is obtained. By this means the tibia is first forced forward and the joint then straightened.

OSTEOTOMY.

Robson [20] reports a series of eighty-four osteotomies on fifty-four patients, sixty-eight for genu valgum, and in these Macewen's osteotome was used. In two cases of bow-legs the saw was used, but in the others a wedge-shaped piece was removed from the tibia. Recovery ensued in all cases, and only nine out of the eighty-four required a second dressing. Of the tibial cases, two suppurated, these two being those on which the saw was used. It was found that unless apparatus was worn there was a tendency for the deformity to return.

ANTERIOR TIBIAL CURVES.

Willard,[21] in a paper on surgical treatment of anterior tibial curves, gives the following conclusions: —

Anterior tibial curves, during the soft and springy stages, may be corrected by manual rectification and the use of apparatus.

Braces are useless after hardening has occurred.

Manual fracture is the best and safest remedial operation in young children.

Instrumental fracture or osteoclasis is not as safe or effective as osteotomy.

Aseptic simple osteotomy for all moderate degrees of curve, and cuneiform section for very severe grades, give almost uniformly good and speedy results without suppuration. Subcutaneous section by the saw is also a reliable operation.

Plaster of Paris is the simplest and most effective material for securing accurate position and maintaining absolute fixation.

Reports of Societies.

FORTIETH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION,

HELD AT NEWPORT, R. I., JUNE 25TH TO 29TH, 1889.[1]

SECTION FOR MEDICINE, MATERIA MEDICA, AND HYGIENE — CHAIRMAN, DR. F. C. SHATTUCK, BOSTON.

Second Day — June 26, 1889.

Dr. FRANCIS DELAFIELD, of New York, opened the meeting with a paper on

[20] Brit. Med. Jour., Jan. 19, 1889, 124.
[21] Med. and Surg. Rep., 1889, Jan. 9, 65.
[1] Continued from page 21.

CHRONIC ENDOCARDITIS.

Of the ordinary diseases few were more common or presented a greater variety and severity of symptoms than chronic endocarditis. It seemed evident that nearly all of the most important symptoms of chronic endocarditis were due to the disturbances produced in the distribution of the blood throughout the body. Why was it that in some cases there were disturbances to the circulation and in others not? The disturbances to the circulation were due to a number of causes which acted singly or together, viz.: —

1, The endocarditis; 2, the dilatation and hypertrophy of the ventricles; 3, the inflammation or degeneration of the wall of the heart; 4, the inflammation of the coronary arteries; 5, the abnormal heart-action: 6, the associated pulmonary emphysema, chronic endarteritis, and chronic Bright's disease. The reader confined himself to the consideration of three which were perhaps the most important: —

(*a*) Endocarditis. Some of the persons with valvular lesions were suffering from chronic endocarditis and others only from the changes produced in the valves by an endocarditis which no longer existed; in the one case they were suffering from the chronic inflammation, in the other from the deformity. Chronic endocarditis might directly follow acute endocarditis, or it might from the first be a chronic lesion; when once commenced it seemed to have a tendency to persist and involve other portions of the endocardium. It was possible, apparently, for the endocarditis to stop at any time, in which case the valves would undergo no further changes. It was a productive inflammation without exudation. In its most active form there was a very considerable growth of cells, and also a death of cells, so that the inflamed endocardium was thickened in some places, ulcerated in others, and on the roughened surfaces thus made thrombi were formed. In its more chronic form the growth of cells was not as great, the cells did not die, the surface of the endocardium was somewhat roughened and small vegetations often formed, but no thrombi.

In other forms of inflammation there might be added degeneration or calcification to the inflamed endocardium and to the thrombi.

In the more active form of the disease many cases ran their course in six months, the symptoms being disturbed heart-action, delirium, convulsions, paraplegia, cough, hæmoptysis, dyspnœa, nausea and vomiting, dropsy, loss of flesh and strength, anæmia, rise of temperature. There might be intermissions and the inflammation might stop altogether. In the slow form the disease lasted many years; there were usually intermissions, and it might stop altogether at any time. Many of the patients had no symptoms, or one symptom might develop and others be added.

(*b*) The abnormal heart-action. The heart's action, as a rule, was disturbed. Such disturbance was produced (1), by the endocarditis existing as an inflammation of some activity and producing changes in the heart's action; (2) there was such a degree of stenosis or insufficiency of the valves as would mechanically interfere with the heart's action; (3) dilatation and hypertrophy of the ventricles

were often present and had their effect in changing the character of the heart's action; (4) chronic myocarditis and disease of the coronary arteries produced the most extreme and intractable disturbance of the heart's action; (5) contraction of the smaller arteries throughout the body, with increase of arterial tension and venous congestion. Such a contraction might last for hours, days, or months. There might be but one such attack or many. With such contraction the heart's action becomes rapid, forcible, or feeble, or tumultuous. The degree of cardiac disturbance was, apparently, in proportion to the suddenness of the contraction of the arteries, not related to the severity or extent of the endocarditis; (6) there were unknown causes, which apparently acted through the nerves, which regulated the action of the heart. In some of these cases the abnormal heart-action was associated with advanced disease of the valves; the pulse was of low tension, feeble and rapid, the heart's action feeble or exaggerated, the condition of the patient often very bad. In still other cases the endocarditis was not advanced, the valves but slightly narrowed or insufficient, little or no change in the size of the heart. The heart's action, however, was rapid, either feeble or exaggerated, pulse soft and rapid. The patients often had pain or abnormal sensations referred to the heart; the general health might be very much impaired.

(*c*) The secondary and complicating changes in the kidneys. Of the persons who suffered from chronic endocarditis a large number never had any complicating disease of the kidneys at all. In the persons who died from endocarditis it was, on the other hand, rare to find normal kidneys. During life it was not sufficient to examine for albumen and casts, which were often absent, but the quantity of the urine, specific gravity, proportion of urea to the ounce of urine, must be determined. Advanced changes in the kidneys often existed in persons whose urine was said after a superficial examination to be normal. In persons who died from chronic endocarditis we might find either chronic congestion of the kidney, chronic degeneration, or chronic nephritis. Three forms of chronic nephritis were likely to be associated with chronic endocarditis: (1) chronic nephritis with a large and continued exudation of serum from the blood-vessels of the kidney into the tubes; (2) chronic nephritis with moderate and intermittent exudation from the blood-vessels; (3) chronic nephritis with little or no exudation from the blood-vessels and the nephritis advancing very slowly indeed.

DISCUSSION.

DR. WILLIAM PEPPER, Philadelphia, said he was particularly glad to hear Dr. Delafield dwell so largely on the state of the arteries, emphasizing the fact that most of the clinical troubles in chronic endocarditis were troubles of the distribution of the blood, while recognizing that there were troubles from the progress of the central lesion. If we knew more of the state of the nervous ganglia about the heart we should add a point of great interest. One could not sum up, he thought, better than Dr. Delafield had done the difference between the classes of cases of chronic endocarditis — "some a deformity; some a chronic inflammation." When it was a progressive inflammation, rest in bed was essential. The causes of this inflammation, their relations to antecedent diseases, were very obscure. The cases where there was not the evidence of a progressive lesion constituted the bulk of the cases of chronic endocarditis and presented the widest differences. He was disposed to doubt whether a contraction of the arteries lasting for days and even for months could have its origin in a mere nervous cause. It seemed to him that in such cases there must exist some progressive organic change in the arterial walls, the relations of which with valvular disease of the heart and disease or changes in the walls of the heart were shown to be more and more close and important. Again, the relations of the valvular disease and the state of the heart to the amount of blood to be moved seemed to him to be a practical thought of the very greatest moment. Here was an organ where there was perhaps no active lesion progressing, yet it was a deformed organ, and it was called upon for mechanical labor above all things. The amount of work to be done was measured by the resistance to be overcome on the part of the arteries and by the mass of blood to be moved; and in dealing with these cases he thought the careful adjustment and regulation of the amount of blood to the needs of the system was a fundamental thought, and therein came the importance of our more accurate systems of diet, as weighing the patient, determining the excreta carefully, and, further, the importance of depleting treatment, whether by saline mineral waters or carefully repeated small venesections, from which we saw the most remarkable results. Again the mass of the body, the amount of tissue to be supplied with blood by the heart, seemed to him to be a fundamental thought in our dealing with endocarditis. The blood might be deficient, but the amount of adipose through which the blood was to be forced, which increased the work of the crippled heart, must exert an immense influence upon the capacity of the heart to do its work. Some of the cases were anæmic and needed to be fed up; many of them which seemed to be anæmic needed to be reduced in weight. Lastly the tone of the tissue appeared to him to be of enormous importance. We must recognize the difficulty the heart had in driving blood through flabby tissue; add to this the danger that the surface of the body was relaxed, the secretion checked, blood driven centrally, fresh congestion possibly of the endocardium excited, and we saw the reason why, despite all treatment, there would be repeated attacks and the development of more and more unfavorable symptoms. Attack the defective tone of the system by massage, by graduated exercises, associated with careful diet and careful regulation of the amount of blood — that seemed to him the most favorable method of treating and of giving the best results in these cases of chronic endocarditis where there was not actual progress of the inflammation existing.

DR. WILLIAM OSLER, of Baltimore, said that chronic endocarditis in itself and by itself produced symptoms no more than any other sclerosis. There were, it was true, certain instances in which the degeneration in the atheromatous valves did produce symptoms, but in the majority of these cases no symptoms were produced directly by the endocardi-

tis itself. Take the case of a chronic, gradually oncoming stenosis of the mitral valve: it was not the endocarditis which had deformed that valve which produced the symptoms, but the gradual failure in the compensation of the heart. Symptoms were produced, first, when compensation failed; it was a muscular change, and frequently noticed as a result of the degeneration in the coronary arteries; and, secondly, in the great majority of cases in connection with neurotic changes of which we as yet knew very little.

Dr. William Osler, of Johns Hopkins University, then reported a case of

SENSORY APHASIA,

and exhibited the brain.

Only about one dozen cases of word blindness are now on record, and this was a very typical case. Patient could not pronounce the words he saw, but could repeat them. His words were constantly misplaced. He finally died with paralysis.

Dr. Osler also exhibited some specimens of brains, prepared according to the Italian method, with zinc, zinc chloride, glycerine, etc.

The third paper was by Dr. James Tyson, of Philadelphia, on

THE INDUCTION OF PREMATURE LABOR IN BRIGHT'S DISEASE.

The occasions justifying the induction of premature labor are (in the judgment of the reader) two in number: —

1. In Bright's disease complicating pregnancy, where puerperal convulsions attended nephritis in a previous pregnancy.

2. In all primiparæ where Bright's disease had existed previous to pregnancy. Here premature labor should be induced as soon as the fœtus is viable.

There is a third class of cases which are not included in the above categories. There may be no urgent reason for interference. Many go to full term, many miscarry. The supervention of uræmic symptoms calls for immediate delivery. The robust and plethoric are in greater danger than the anæmic and feeble. Bright's disease in a first pregnancy is generally more serious than Bright's disease in subsequent pregnancies.

Dr. V. C. Vaughan, of Michigan, said that some women habitually have uræmic symptoms in pregnancy. By uræmia he means blood poisoned by urinary elements. Where such symptoms present themselves, labor should be induced early. Three patients under his care in three successive labors had puerperal convulsions. The symptoms came on suddenly; there were large quantities of albumen in the urine, and the secretion was scanty. He would never think of allowing such cases to go full term. In primiparæ we are not justified in being so hasty, or in formulating any law.

We can do much to lessen the liability to danger by dieting. The appearance of swelling of the extremities, puffiness under the eyes, albumen in the urine, would lead him to limit the amount of proteids in the food of his patient. He would allow meat only once a day, and would choose the white in preference to the dark meats; milk should be the principal element of diet in many cases. He would promote elimination by a dose of Carlsbad salts in the morning.

Dr. Atkinson, of Baltimore, thought that the contracted kidney was most prolific of puerperal convulsions and of danger in pregnancy. He always waits for the supervention of uræmic symptoms before interfering.

Dr. Scott, of Cleveland, treats the pregnant albuminuric by milk diet, scanty proteids, and tincture ferri chloridi. He had had in one patient seven miscarriages in eight years, and recovery. He believed that patients who had had scarlatinous nephritis in childhood were apt to have Bright's disease during pregnancy.

Dr. Stewart, of New York, said that one difficulty in the management of Bright's disease of pregnancy was to obtain the consent of the patient and family when the induction of premature labor seemed a necessity to the attending physician.

Dr. C. N. Chamberlain, of Lawrence, and Dr. J. C. Wilson, of Philadelphia, corroborated the views of the previous speakers.

Dr. Tyson, in closing, emphasized the proposition that in primiparæ the existence of Bright's disease prior to pregnancy makes the disease much more serious. In multiparæ we may have albumen in the urine over and over again without seriousness. But where there are bad uræmic symptoms with tube-casts, then it is time to interfere.

Dr. D. W. Prentiss, of Washington, D. C., read a paper on

THE PHARMACOPŒIA OF 1890.

It is important that the physicians of the United States should be represented in the revision of the Pharmacopœia, and the American Medical Association should appoint three delegates to be members of the Committee of Revision, in accordance with a provision of the statutes.

A resolution was carried that the chairman of the section should offer a motion to this effect at the general meeting.

ON REYNAUD'S DISEASE.

Dr. G. M. Garland read a paper with the above title.

Maurice Reynaud was the first (in 1862) to describe a peculiar affection to which he gave the name of "symmetrical gangrene of the extremities." He collected twenty-eight cases observed in the hospitals of Paris, and after analyzing the symptoms defined the disease as "a neurosis characterized by an exaggeration of the excito-motor power of the cord presiding over the vaso-motor nerves." He believed that there was no alteration of the heart or arteries in these cases, consequently denied that the gangrene was due to arterial occlusion, whether by hyperplastic endarteritis, by thrombosis, or by embolism. He called particular attention to the spasm of the vessels, and proposed the name "local asphyxia" to designate the peculiar condition of the parts affected.

A great many cases have since been reported, and the disease has been duly recognized as a definite nervous affection by leading authorities in all countries.

The reader described three stages: 1. The stage of local syncope; if in the fingers, these are cold, dead, anæsthetic, *digiti mortui*. The temperature is

lowered, the parts seem frozen. The return to the normal state is accompanied by light prickling or burning sensations. The duration of this stage may vary from a few moments to several days. This stage may be succeeded by a second, of cyanosis. 2. Local asphyxia. This is a stage in which the exit of venous blood is impeded; the vascular spasm is intense; the capillaries are engorged, and the members have a bluish appearance, are cold and painful. The return to color and temperature may be very rapid, or very slow. 3. The stage of symmetrical gangrene generally develops out of the asphyxiated stage. The gangrene is generally of the dry mummified kind, although it may be moist. The member sometimes undergoes spontaneous amputation in ten days. The gangrene may affect other parts of the body than the toes and fingers; sometimes both ears, the lips, or symmetrical parts of the nose.

Theories — (*a*) angio-neurosis (Reynaud);
(*b*) tropho-neurosis;
(*c*) endarteritis obliterans;
(*d*) local neuritis.

Etiology — exposure to cold (frost-bite), sclerodema, syphilis, malaria, anæmia, abuse of morphine, Bright's disease, diabetes. (Etiology is obscure.)

The internal treatment has been unsatisfactory. Dr. Garland reported three cases occurring under his own observation.

The above paper was discussed by Dr. C. N. Chamberlain, of Massachusetts, Dr. Herrick, of Ohio, and Dr. Holden, of Vermont.

DR. HERRICK thinks that there may be many types of symmetrical gangrene, and that they are all phases of perverted nutrition — disturbance of the crasis of the blood, disturbance of the circulating vessels, disturbance of the nutrition of the cells of the part. In treatment we should take cognizance of the factors of causation.

DR. GARLAND, in closing, remarked that the disease often occurs in young people otherwise healthy, and that at the autopsy there have been no changes noted that throw light on the causation.

The next paper was by DR. J. V. SHOEMAKER, of Philadelphia, on

DIOSCOREA VILLOSA — WILD YAM.

This indigenous plant was believed by the reader to be of singular efficacy as a remedy in intestinal and hepatic colic. In the latter disease it will generally relieve without morphine; in fact hardly any other medicine is needed. The dose of the decoction is from one to four fluid ounces; of the tincture ten to sixty drops; of the fluid extract, five to thirty drops. Large doses are emetic. It is diaphoretic, antispasmodic, expectorant, and cholagogue.

SECTION FOR SURGERY AND ANATOMY — DR. N. P. DANDRIDGE, CINCINNATI, CHAIRMAN.

Second Day — Wednesday, June 26, 1889.

The first paper of the afternoon was by DR. C. B. PORTER, of Boston, on

EXTROVERSION OF THE BLADDER.

Dr. Porter said that this was a congenital deformity, in which the bladder, with mucus surface exposed, protruded hernia-like in the lower hypochondriac region. Its anterior wall and corresponding portion of the abdominal walls were wanting, with usually the symphysis pubis. The urine dribbled from the ureters or was ejaculated in squirts on coughing or sneezing. Its constant contact excoriated the skin of the genitals and thighs and made its possessor miserable, and the attending urinous odor an object of repugnance to those about. The other parts of the genito-urinary system were usually present in a more or less developed state.

Dr. Porter's cases presented one of each sex. Although this deformity was distressing, patients with it lived many years.

The reader then reviewed the different operations that had been done for the relief of this deformity.

With regard to the choice of operation it seemed to the writer that age and the extent of the cleft must determine. Up to the present time no operation had attained continence of urine. The results of diverting the urine into the intestine were not encouraging; diverting the urine to a central point in the abdominal wall did not commend itself. Trendelnberg's operation had thus far achieved no more than the method by flaps. This method was one adapted to both sexes and to all ages.

The surgeon, before operation, should inform himself as to the condition of the kidneys, and continually keep in mind the main result for which he was striving, namely, the free drainage of the urine, otherwise obstruction with its results — dilatation of the ureters and destruction of the kidneys — would ultimately follow. The development of the prepuce and scrotum in the male, the labia minora and majora in the female, furnished the operator abundant material for flaps. All the general rules of plastic surgery held in these operations. The flaps must be about a third larger than the gap to be filled. They must be arranged in such a manner as to furnish to their pedicles an abundant supply of blood. During any delays in the operation they should be covered in hot towels wet in an antiseptic solution. They must be handled as little as possible, and rarely with forceps. Any dragging on the pedicle endangered the vitality of the flap. All bleeding must be arrested before the flaps were adjusted in position. Light and gentle pressure prevented any oozing between them. The operation completed, they should be kept for many hours in moist, hot, antiseptic dressings. Perfect antisepsis should be maintained throughout. The reader reported two cases which were operated upon in accordance with these rules. In both the operation was successful. Case 2 was that of a girl of eight years of age. She was healthy and well formed, with the exception of the extroversion of the bladder, which was complete. The cleft extended from the mons veneris, symphysis pubis, and urethra into the vagina, which was split throughout, and formed a sort of trough down which the urine ran when she was in the upright position. The pubes were separated three inches. The mucous membrane of the bladder and vagina was exposed, bleeding on the slightest irritation. The ureters opened near the middle of this exposed surface an inch apart, and on coughing the urine was forced out in small jets. On straining, the exposed bladder bulged out, forming quite a hernia. Surrounding the bladder was a ring of

cicatricial tissue one-half inch wide. By the most careful rectal examination under ether, no uterus or uterine appendages could be felt.

Operation January 11, 1889; ether. A pattern in cloth was cut of a size required to cover the exposed surface. A flap of skin one-third larger than the pattern, to allow for shrinkage, was raised from the middle of the abdomen, between the bladder and sternum. Its pedicle, which was broad, was attached just above the bladder. The flap was temporarily covered with towels wet in a hot solution of boric acid. Two side flaps, each one-half the size of the large flap, were then cut from the pubic and inguinal region, with pedicle at the side of the split mons veneris. These were folded in hot, wet towels. The skin around the bladder was then raised up about one-half inch, making a raw groove running around the margin of the vesical wall, where it blended with the integument, except a small area which corresponded to the split vagina. The large abdominal flap was then turned down, with the skin surface next the mucous membrane, and the edges stitched into the groove above mentioned with fine catgut, leaving only on the middle line a canal for the passage of urine formed by the vagina. The two side flaps were then swung around towards the middle line, and their raw surfaces opposed to the raw surface of the abdominal flap. They were stitched to each other on the middle line, and at their circumference to the same groove as the abdominal flap. In this manner a complete cover for the bladder was made. The abdominal wound, from which the broad flap was taken, was brought together by stitches in the middle line. The two internal wounds were left to close by granulation. The double rubber drainage-tube was placed in the bladder thus formed. The seat of operation was covered with towels wet in a hot 3% boracic solution, and they were changed frequently for a number of days. The girl made a rapid recovery, the wounds closing by first intention except those on the side purposely left open to avoid traction on the flaps, and in less than three months she was dressed and playing about the wards. A plaster cast was taken of the parts, and a hard rubber shield with urinal attached was fitted. This the patient still wore. The patient, now a fine, healthy girl, was presented to the association.

Dr. W. T. Briggs, Nashville, Tenn., read a paper on

THE CHOICE OF OPERATIONS FOR THE REMOVAL OF URINARY CALCULI.

It can hardly be said that there is any best operation; that is best which is best performed.

In determining the choice of operation, the various conditions of the patient and of the stone are to be considered. Lithotomy has been very successful in patients under twelve years. Gross reports one death in thirty-six. The reader had had seventy-one cases: all were successful. The operation is quick, easy, and safe. Litholapaxy in children is more difficult and dangerous.

After puberty the crushing operation is generally the best. In advanced age the increased size of the prostate, the lessened resistance to morbific causes, the proneness to suffer from inflammations of the urinary organs, etc., make every operation hazardous. Litholapaxy is the best operation. The reader stated that in his experience lithotomy has been attended with good results even in the aged. Old age alone does not constitute a barrier to either operation.

Where the stone is small, soft, and smooth it is easily crushed. Where it is hard, large, of urates or oxalates, it often resists the lithotrite. Where, then, the stone is large and indurated, encysted, and sacculated, where there are old, indurated, tortuous strictures, where the urethra is intolerant, where there are prostatic enlargements, overgrowths, and tumors with residual and putrid urine, where there is severe and chronic inflammation of the bladder, he would perform lithotomy.

Lithotrity is now superseded by Biglow's method; the operation is completed in one sitting; is more successful than the old method.

Methods of lithotomy: 1. Supra-pubic method. Mortality, 30%. This method is advisable (*a*) when the stone is of large size, and not easily removable by an incision in the urethra being from one and a half to two inches in diameter; (*b*) when the calculus is lodged high up behind the pubes, and is more accessible by a supra-pubic incision; (*c*) in deformity of the pelvis, with narrowing of the inferior strait; (*d*) where there is great prostatic enlargement and concentric hypertrophy of the neck and base of the bladder. A very large stone cannot well be brought through the urethra and perineum without lacerations.

2. The lateral method: This is the most frequent method; is the most dangerous as to hæmorrhage; is the most likely to wound the prostatic capsule.

3. The median operation: Is the best. There is less section of tissue than in the other methods. The raphe is the safest point for the extraction of stone. But a large calculus cannot well be removed by this incision. If to the median a moderate bilateral incision be added, made in the deeper seated structures, the dilatability of the prostate and perineum is almost incalculable. This operation he styles the *medio-bilateral*. It is the shortest and most direct road to the bladder, and divides parts of the least importance. There is no danger of wounding the seminal ducts. The operation is almost bloodless. The median operation gives plenty of room for a middle-sized stone, but if you add to this operation a nick on either side of the neck of the bladder, the deep-seated parts admit of extension to almost any degree. This lateral nick (made by a scissors invented for the purpose by the reader) need not be more than six lines in extent. If the stone be too large to be easily removed, it may be fragmented.

The median or medio-lateral method leaves the parts in the best condition for drainage. The wound often heals by first intention. Out of Dr. Briggs' 136 cases, there were but three deaths.

Dr. A. T. Cabot, of Boston, read a paper on

LITHOLAPAXY.

In Dr. Cabot's opinion litholapaxy was the operation of choice for the removal of most stones. In modern surgery the test of merit was determined by the results. The best operation was the one which saved the most patients, other things being

equal. There were three methods of operation to choose from: (*a*) perineal lithotomy,—median and lateral; (*b*) supra-pubic lithotomy; (*c*) litholapaxy. Each had advantages, and each dangers and difficulties to be recognized and avoided. Each case must be studied for itself, and that operation chosen which would best meet the difficulties and avoid the dangers of that particular case.

We could not compare the results in patients at very different ages. The mortality of children after operation upon the bladder was distinctly less than in those of advanced ages.

Cases might be grouped under three categories: (1) children up to fourteen years; (2) adults from fourteen to fifty years; (3) old men from fifty years upwards. This, of course, was somewhat arbitrary.

Owing to recent improvements in technique and the influence of the adoption of general antiseptic methods the statistics of old times could not be accepted.

TABLE I. — Statistics of perineal lithotomy. Number of cases collected in children, 355: mortality 3.1%; in adults, 79 cases: mortality 7.6%; in old men, 19 cases: mortality 15.7%. Freyer collected 987 cases. In these the rate of mortality up to twenty years was 5.1%; from twenty to forty 10.7%; above forty 31.9%. Rosenthal in 400 cases gave the following: one to five years, mortality 3.5%; six to eleven, mortality 2.1%; twelve to sixteen, 8.4%; seventeen to twenty-nine, 15.7%; above thirty, 38.8%.

TABLE II. — Statistics of supra-pubic lithotomy. Number of cases collected in children, 265: mortality 10.9%. In these were included the phenomenal statistics of Assendelft, of Russia — 103 cases without a death. In old men the mortality was 42.1%.

TABLE III. — Statistics of litholapaxy. Number of cases collected in children, 115: mortality 3.5%; in adults, 149: mortality 5.3%; in old men 188: mortality 8%. Guyon had a mortality of 5.2% in 647 cases of all ages.

In children, therefore, judging from the mortality, there was little choice between lithotomy and litholapaxy. Supra-pubic lithotomy was a little more dangerous.

It was somewhat unusual to see serious interference with the functions of the parts. Supra-pubic incision sometimes caused fistulous opening. Perineal operations were much more likely to cause serious trouble. The lateral incision had the advantage of giving more room and of endangering only one duct. Incontinence occasionally resulted from perineal incision owing to interference with both sphincters of the bladder; and fistulæ, though rare, sometimes occurred, and might be persistent and troublesome.

In regard to completeness of cure, it was not uncommon to see a second or third attack of stone in the same patient, (1) on account of persistence or reappearance of the uric acid diathesis: the same might be true of the oxalate of lime stone; (2) successive escape of several stones from the kidneys might give rise to successive stones in the bladder; (3) several phosphatic stones might be reproduced after removal if the chronic cystitis and alkaline urine which led to the original formation persisted; (4) if a fragment was left after the operation it might serve as a nucleus of another stone. A healthy bladder that completely expelled the urine usually freed itself of such fragments.

Selection of operation: With children it would seem wise to use litholapaxy for all small stones, — stones up to two centimetres in diameter. This operation did not involve danger to the seminal ducts and did not give rise to fistulæ and incontinence of urine. Litholapaxy was the operation of choice in adults. Stones weighing 2000 to 3000 grains had been crushed and removed. A large and very hard stone might resist every attempt at crushing, and the stone might have as a nucleus a foreign body too hard to crush. Stricture of the urethra might prohibit litholapaxy. False passages might exist which so interfered with the introduction of instruments that the dangers of the operation were enhanced. The stone might be so lodged in the entrance to the urethra that it could not be pushed back and seized with the lithotrite. Occasionally cases were met with in which the prostate was so large that the stone could not be reached. The supra-pubic operation would apply to most cases not to be dealt with by litholapaxy.

DR. DUDLEY P. ALLEN, of Cleveland, read a paper on

LITHOLAPAXY IN CHILDREN.

The object of the paper was to point out the cases to which this operation was adapted. The reader alluded to Freyer's results with the lateral lithotomy, and expressed the opinion that with time and experience litholapaxy might yield similar results. In cases of large calculi the supra-pubic operation had its advantage on account of the difficulty, in case litholapaxy was done, of pumping out the fragments. Litholapaxy was not a cutting operation, and there was not likely to be so much delay before patients submitted to operation. In cutting operations union by first intention was rare in any save the supra-pubic method. Thus far no operation confined the patient to bed so short a time as litholapaxy, and it could in no way injure the reproductive apparatus. The advantage gained by seeing the interior of the bladder, as in the supra-pubic method, had been urged as a point in favor of that operation. In boys, however, encysted stones were uncommon and the bladder was usually in a healthy condition, so that the necessity of seeing its interior was small. One great difficulty in litholapaxy was the small size of the instruments that must be used. In some cases, even after incising the meatus, the urethra was so small that the instrument could not be introduced. Where an operator found a very large stone, it would be better to abandon litholapaxy and do lithotomy.

Beyond question, the operation of litholapaxy in children was one which must be recognized as particularly suited to medium and small sized stones, and though medium and lateral lithotomy were very successful in such cases, he believed litholapaxy would be equally successful in skilled hands. It had the advantage of absence of cutting, of slight suffering, and of short confinement. In case of return of stone, the second operation would be more easy than the first on account of the

increase in the size of the urethra with the increase in age. Large and hard stones should be removed by the supra-pubic operation, especially if for any reason it was desirable to see the interior of the bladder. Median lithotomy was favorable in cases of small stone. In case of medium-sized stone, where the urethra was not large enough for the introduction of the instrument, lateral lithotomy was indicated.

DR. J. W. S. GOULEY, of New York, in opening the discussion, said the operation of lithotrity was indicated in cases where the stone was free, friable, and of small or medium size. In certain cases, plurality of stones was not a contraindication. The patient should be in otherwise good physical condition, urethra ample or susceptible of being rendered so. The existence of stricture was not a contraindication to cysto-lithotrity, provided the urethra could be freely dilated or enlarged by internal incision; but a narrow stricture in the perineal region contraindicated lithotrity by the perineal route and generally demanded cutting operation. In cases of thick bars at the neck of the bladder, and tumors of the prostate, lithotrity was not always practicable and cutting operation sometimes required. When the bladder contracted and its capacity was markedly diminished, or it was irritable, perineal cystotomy was indicated and lithotrity contraindicated. Advanced disease of the bladder, ureters, and kidneys contraindicated both lithotomy and lithotrity.

As a general rule, multiple short sittings (one to three minutes) were applicable to patients whose bladders were only moderately tolerant, three or four such sittings, with the introduction of the lithotrite, four or five days apart, usually being sufficient to cause the spontaneous expulsion of all detritus of friable stones one inch in diameter. One or two long sittings (ten to fifteen minutes), with five or six introductions of the lithotrite, sometimes sufficed to remove from tolerant bladders the major part of a friable stone one to one and one-fourth inches in diameter, the remainder of the detritus being spontaneously expelled. Cysto-lithotrity at one sitting, with aspiration of the detritus, was said to be contraindicated when the stone was large and there existed urethro-vesical obstruction, but it was often performed in violation of both these contraindications. The sittings of lithotrity averaged two minutes. Prudence demanded intervals of four days between sittings, twelve days in all being consumed in effecting a cure. His own cases were ambulant cases.

Against litholapaxy it might be said that the sittings lasted two hours; that the process of aspiration itself was so much more painful than the crushing that anæsthesia was rendered necessary, and this objection was well taken when we considered the ill effects on the kidneys from the inhalation of sulphuric ether in case anæsthesia was to be prolonged one or two hours. Litholapaxy was no longer a novel operation, having been performed many hundred times since 1878. The great expectations of its advocates were not realized, for the operation could not always be terminated at one sitting; it was not suitable in a number of cases of large stones; it was not applicable in many cases of stone complicated with prostatic obstruction. It had been too often misapplied by the over-zealous to medium-sized and small stones adapted to lithotrity at one or two short sittings. In many cases the injury inflicted upon the bladder had led to cystitis and the formation of phosphatic stones; and with the necessarily prolonged anæsthesia the operation was too dangerous to be generally employed. Litholapaxy applied to a very limited class of cases was a very good operation in the hands of skilled and experienced lithotritists, but too much of an undertaking for beginners or those not constantly occupied with surgery. That many bladders had been sacrificed in this way was no fault of the operation, but of the operator.

In cases of small friable stones weighing a few grains the operation of lithotrity was justifiable and safe in children under five years of age; lithotomy was safer in such children when the stone exceeded one-half inch in diameter.

The general conclusion of the reader was that the proper choice of treatment of urinary concretions could only be made after careful consideration of each method and each case, there being no generalizable method.

In reply to a question in regard to vesical irritation by fragments Dr. Gouley said he thought that was generally very greatly exaggerated. The sharp, angular fragments of the worst kinds of stones did less harm than we were asked to believe. The epithelium of the bladder had the property of throwing out on the slightest irritation a considerable amount of thick mucus so called, which adhered to the fragments, forming an envelope which was so protective that the fragments of such size as would pass spontaneously through the urethra slipped out without causing much irritation. Sixty per cent. of the stones of diathetic origin consisted of uric acid and the urates. These stones of uric acid and the urates were highly granulable and underwent disgregation, without disintegration of the particles, upon the ingestion for several weeks of the potash salts. Now the lithotrite effected the same result without any alkali. The great majority of stones could be crunched into a coarse powder or granular state; and these granules of uric acid caused little or no irritation and were passed out. He frequently crushed these stones in this way, in his office, without pain and without anæsthesia.

DR. R. T. MORRIS read a paper on

WHAT DRESSING SHOULD LIE NEXT TO THE WOUND?

Dr. Morris alluded to the various methods of dressing wounds, and said that if we applied any textile fabric, as bichloride gauze, etc., the connective tissue cells would shoot into the fabric and delay healing, and if such dressings had to be removed we destroyed a large part of the tissue nature had put across the wound for purposes of repair. To obviate such a result he recommended the use of Lister's protective oiled silk, in that the connective tissue cells became organized with the greatest ease and without the irritation that followed the application of any of the textile fabrics. In the suppurating wound, to get clot replacement was almost impossible by any other means. In skin grafting, the little cells shooting out would penetrate any

textile fabric and the graft might die. If, however, Lister's protective oiled silk, properly prepared, were placed next the graft the result would be striking; the thin blue film of epithelium remaining undisturbed was an evidence that we had covered our grafts with the best dressing. In wounds containing pus we must first use peroxide of hydrogen to make the granulating wound chemically clean, and over that Lister's oiled silk, and then no more pus would form.

Over the Lister oiled silk we could apply any absorbent dressing we wished — bichloride gauze, salicylated gauze or cotton, or any of the absorbent dressings, which dried it so that micro-organisms could not grow in it readily.

DISCUSSION.

DR. H. O. MARCY, Boston, said he agreed in very large measure with Dr. Morris with reference to the wound he had under discussion. He had long treated them by Dr. Morris's method; and the use of Lister protective dressing in a wound that must necessarily be a granulating wound, and which had been rendered aseptic, gave better results in his hands than any other dressing. In an operative wound, however, he would differ from the reader. In such wounds the coaptation must be absolute and the wound aseptic. The edges of the skin being in close apposition needed no other protection than just drying them by blowing on iodoform. Then a few layers of cotton completed the dressing. This left nature entirely to herself, not a stitch to remove, the tendon suture having been used, nothing to drain, no effusion, agglutination and repair went on rapidly.

DR. PANCOAST, Philadelphia, called attention to iron-dyed black silk he had had made and was in the habit of using. White silk was dyed with lead and was not pure silk; when dyed with iron and washed with acetic acid it was pure silk. The fine black silk suture would remain for weeks in the tissues without suppuration or inflammation.

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY,[1]

HELD IN MECHANICS' BUILDING, BOSTON, JUNE 11, 1889.

SECTION IN OBSTETRICS AND GYNÆCOLOGY.

DR. J. B. SWIFT, of Boston, read a paper on

THE THIRD STAGE OF LABOR.

The third stage of labor was the period following the birth of the child until the placenta has been delivered and firm uterine contractions established.

Dr. Swift reviewed the theories of Baudelocque, Schultze, and others as to how the placenta became separated.

In all probability the normal separation of the placenta and membranes did not take place until after the birth of the child.

As to the management of the third stage of labor, there were still advocates of an entirely expectant treatment. It was claimed that by the expectant method there was a better separation of the decidua, and the membranes were not so apt to be retained; but, on the other hand, more blood was lost, and uterine relaxation took place, allowing clots to form in the uterus. There were still advocates of traction on the cord, but most of them advised that the traction should not be too strong, and should be combined with pressure on the uterus by the other hand.

His own method was to follow the uterus down with the left hand, which was kept on the uterus till the binder was applied, and sometimes later. The cord was tied and cut and the child put one side. Then the patient being turned upon the back he waited until the uterus was felt to contract, and if the sensation of something passing out of it was felt and it was growing smaller, with the hand spread out over the uterus he pressed gently downwards in the direction of the axis of the pelvic brim. The placenta, as it appeared at the vulva, was caught in the right hand and twisted around, while being drawn out, so as to roll up the membranes. The placenta being born, the uterus was still held by the left hand, a dose of ergot administered, the soiled clothes removed as far as possible from beneath the patient, a wad of antiseptic cotton placed over the vulva, and the physician sat by the bed with his hand holding the uterus while the nurse was washing and dressing the baby, which took about an hour. Then the patient's toilet was attended to and the binder applied.

If after twenty minutes by the watch contractions had not begun we might in most cases endeavor to excite them. It was the duty of the physician to hold the uterus himself.

DR. C. M. GREEN, of Boston, said he agreed with the reader as to the duty of the physician during the third stage of labor. A great deal of post-partum hæmorrhage was due, he believed, to the fact that the uterus was left to take care of itself too soon after the child was born and the placenta delivered.

After the birth of the child he was in the habit of stimulating uterine contractions by cupping the fundus with the left hand and exercising a sort of circular friction movement over the fundus, but did not at that time use force upon the uterus. If one-half hour passed without successful contractions he would exercise the Crédé method. While the nurse was bathing the patient and removing the soiled clothes he still kept his hand upon the fundus. When the woman was ready for the binder he padded the uterus and adjusted the binder himself.

DR. EDWARD REYNOLDS, of Boston, thought that so long as the uterus was watched by the hand to a degree sufficient to prevent post-partum hæmorrhage, it made very little difference to the patient what method was used in the application of Crédé's method. The uterus should not be left unguarded by the hand during the third stage. Constant pressure of the hand over the uterus and slight friction movements were sufficient in practically all cases to do away with all post-partum hæmorrhage. He thought he had seen metritis and perimetritis follow too forcible application of Crédé's method. He preferred always to manage the third stage of labor with the patient on the back all the time, and preferred for her not to turn

[1] Continued from page 638.

upon the side at all. Care should be taken not to express the placenta too suddenly and violently in case of an already slightly torn perineum. If the obstetrician's hand was strictly clean early removal of the placenta, though seldom necessary, was a very simple proceeding and one devoid of danger.

DR. J. P. REYNOLDS, of Boston, said he was very sure that a trained hand should be kept over the patient's uterus during the whole toilet. It was remarkable to notice how high the percentage of disease and death was from this simple matter of the expression of the placenta. Rough and careless handling of the uterus was to be strictly avoided. In case, however, the patient presented alarming symptoms, the very first thing was to empty the uterus without a moment's delay.

DR. SINCLAIR, of Boston, said the too hurried withdrawal of the placenta or the too harsh manipulation of the uterus was to be deprecated, although every one knew that one could never be sure of exemption from hæmorrhage unless he had the uterus in the palm of the hand.

DR. W. E. BOARDMAN, of Boston, read a paper on

ASEPTIC OBSTETRICS.

Dr. Boardman's paper was intended to show that puerperal septic disease was scientifically demonstrated to have a bacterial origin, and it was immaterial for our present purpose whether we accepted the chemical or the vital theory of their action; that it was probable that most of the local affections incident to the puerperium belonged to the same septic class of diseases; that these occurred throughout the State, in both rural and urban districts, more commonly than physicians had been willing to admit, and, this being true, it might readily be understood that deaths from this cause, and the much more numerous cases which survived to become more or less chronic invalids, entailed a serious burden upon the welfare and prosperity of families and the State; finally, that the experience in hospitals exhibited the adequacy of due prophylaxis to prevent septic disease.

Dr. Boardman described the various methods which have been employed in the past for the prevention of puerperal septicæmia. The rules adopted, while correct in principle, were defective owing to lack of knowledge as to the precise details required to ward off the disease.

In conclusion, Dr. Boardman called attention to what might now be considered necessary in the way of prophylaxis.

1. Filth implied decomposition and invited the presence of septic germs; hence perfect cleanliness was demanded.

2. The proper contraction of the uterus should be promoted and its proper position secured, so that no obstruction to the exit of lochial discharges should exist.

3. The vulva should frequently be bathed in a disinfecting solution, and after a tedious or laborious labor, or when artificial or instrumental delivery had been necessary, it was important to give a vaginal douche of a hot disinfecting fluid, which should be extended within the uterus if its cavity had been entered by the hand or by instruments, and also if a putrid child had been born.

4. Perineal lacerations should be united, in order to avoid the exposure of extensive raw surfaces to the action of the germs.

5. At the completion of the labor a napkin or towel wet with the disinfecting fluid should be placed against the vulva.

6. Finally, the toilet of the patient was to be made complete, all soiled clothing removed, and the vulvar napkin applied. Both the physician and the nurse should be governed by rigid rules of absolute personal cleanliness. Their hands should be disinfected. Due attention to hygiene, etc.

These rules were especially required during the first week of the lying-in period.

DR. PORTER, of Auburndale, said that in the use of antiseptics in the hospitals and in private practice the mortality had been reduced as much as in small-pox by vaccination and isolation. He wished to draw two inferences: (1) that the discussion of antiseptics in obstetrics had increased the attention to cleanliness, if not the direct use of antiseptics in pregnancy; (2) that it was likely to become in the near future the exception for obstetric cases not to be treated antiseptically.

DR. CRAWFORD, of Roxbury, said she most heartily believed in antisepsis. We could not safely pin our faith to any one of the reputed germicides or trust to them except as accessories to the one certain safeguard — perfect cleanliness of everything about the person of our patient, particularly the instruments, the hands, and the clothing of those who use them. Dr. Crawford spoke of the merits and efficiency of boiling water, or its equivalent, steam, as a germicide. In the cleansing of hollow instruments care should be taken to have the instruments completely filled with the boiling water. Many of our most valuable antiseptic agents were often rendered useless or harmful in the hands of the ignorant or unskilled. There were so many details upon which immunity from danger depended that it might be doubted if the comparatively simple operation of washing out the uterus, for instance, could be left to any except highly skilled obstetricians.

DR. E. M. BUCKINGHAM, of Boston, said he thought that carbolic acid in any strength possible to be injected into the vagina was not an antiseptic to be relied on. He believed the use of moderately carbolized injections of such water as we were likely to get in most places, that was not boiled, was far more dangerous than to let the patient absolutely alone. In making the treatment positively aseptic the toilet of the hands was perhaps the most important thing. He thought the antiseptic pads were unquestionably efficient. A simple and good substitute was the napkin dipped in corrosive sublimate and dried. In the use of the catheter it seemed to him wiser not to use the same catheter for two patients. In two instances he had seen a slight irritation in the urethra from the passage of a catheter which had been wet with corrosive sublimate.

DR. O. H. EVERETT, of Worcester, said he had not adopted the antiseptic treatment to the extent of using corrosive sublimate and carbolic acid as freely as some who had spoken; but he believed in perfect cleanliness, which thus far had been satisfactory; still it had been his fortune to see cases of

puerperal septicæmia, whether from neglect on his part he had not been able to determine.

DR. C. W. STEVENS, of Charlestown, said he had been able to carry out the strict antiseptic treatment in a somewhat modified form among the very poor classes, notwithstanding their ignorance, obduracy, filth, or anything else, because he did it himself. The expense was nothing to them and very slight to him.

DR. Z. B. ADAMS, of Framingham, said he still believed that the use of the douche in normal midwifery was bacteriology run mad. In his opinion, the vaginal or intrauterine douche was indicated in case of foul lochia. There was danger in the use of too weak solutions of carbolic acid and of corrosive sublimate, as well as in the use of too strong solutions. He had seen cases of poisoning produced by mild solutions of bichloride, that would not have been produced by strong solutions: that, however, he would not state as a positive fact. He had nothing to say against the germ theory of disease or the necessity of keeping out the germs in puerperal fever.

DR. DUNBAR, of Boston, wished to put himself on record as an advocate of aseptic midwifery, whether antiseptic was another question. In normal cases he used no douches; but in complicated cases and in all instrumental cases he used injections of corrosive sublimate (1 to 2000) followed by injections of hydronaphthol to wash out any superfluous corrosive sublimate.

DR. MARION, of Brighton, desired to place himself decidedly on the side of asepsis. It was his custom to give a bichloride douche before labor in all cases where there had been a leucorrhœa during the last month or two of gestation, and by so doing he thought there was less ophthalmia in the new-born.

Dr. Marion called attention to linear laceration of the vagina, which occurred sometimes without laceration of the perineum, which, if detected at the time of occurrence and repaired in accordance with the rules laid down by Dr. Emmet, would save a great deal of suffering to the patient in after life, and a very tedious operation later.

DR. J. F. COUCH, of Somerville, said he did not use douches before or after labor: did not douche the genital canal unless there was necessity for so doing. That necessity was evidenced by some peculiar rise in the temperature or some peculiar condition of the patient. He used bichloride on the hands and hydronaphthol on the instruments.

DR. T. S. GREENE, of Dorchester, said he had had less anxiety and less difficulty with his cases since adopting the aseptic method of treatment.

DR. C. M. GREEN, of Boston, said that at the Lying-in Hospital the custom at present was to give a vaginal douche before labor, for the benefit of the child as well as that of the mother. The vaginal douche did not do harm to the mother and did diminish the risk of ophthalmia. In his own private practice he regarded it unnecessary in some cases to give the douche during the first stage. If there had been no leucorrhœa and the lady was of cleanly habits, he did not feel that it was absolutely necessary; nor did he invariably give a douche at the conclusion of labor. Provided the labor was normal, no instruments used, and the examinations few, he did not necessarily do it.

Aseptic midwifery could be carried out among the poor exactly as well as among the rich. In the clinic of the Harvard Medical School, in which the students in the year delivered about five hundred cases, we did not have septicæmia or women sick with septic fever. These women lived in unhygienic quarters, did not have clean sheets, pads — lucky if they had the ordinary towel — and they did not have septicæmia; and why? Because the students were taught to take care of their hands.

He had a supreme contempt for the purported asepsis of a great many. The mixing up of corrosive sublimate and dipping one's hands into it was far from asepsis. The hands should be first washed with soap and water and a good, stiff nail-brush used before they were dipped in corrosive sublimate. He questioned whether it was not our duty after using forceps to boil them. The simple immersion of the forceps in 1 to 20 carbolic would not, he believed, make them thoroughly aseptic. He thought we should not bring discredit upon the practice of aseptic midwifery when the failures were due to our own fault in not taking extreme precautions.

DR. W. E. BOARDMAN, of Boston, in closing the discussion, said there was a difference of opinion with regard to the strength of the solution to be used. As we were not all chemists or bacteriologists we had to rely upon practical experience. He knew of no better practical experience than the experience of the Boston Lying-in Hospital, which had been entirely freed from septicæmia by the means used; and it was fair to presume that the means used were the efficient means to kill bacteria.

DR. C. P. STRONG, of Boston, read a paper on

THE SURGICAL TREATMENT OF BACKWARD DISPLACEMENTS OF THE UTERUS.

Dr. Strong made two distinct divisions of backward displacements: —

1st. Backward displacements which were not adherent. 2nd. Backward displacements in which there existed union by slight or firm adhesions between the uterus and adjacent viscera or pelvic walls.

The treatment of the former class was limited to the best means to be adopted for retaining in its normal position the uterus which cannot be replaced manually; in the latter, the additional consideration of how first the uterus might be freed from its abnormal position and subsequently secured.

The simplest plan for the separation of the adhesions was rupture or tearing off the adhesions without any cutting operation. During the past three years he had done the Schultze operation, somewhat modified, in more than twenty cases. Only two required further surgical treatment for a recurrent displacement.

It was unwise to attempt a forcible reposition if there was present any acute inflammatory process; if the adhesions connected the fundus in broad bands with the investing membranes of the rectum; if the adhesions were found to be lateral, involving, as they probably do in that case, the tubes or

ovaries, or both; if they had resulted from an attack of general peritonitis; if it was fairly probable that tubular disease is present.

In the treatment of the non-adherent backward displacement the problem to be solved was to perfectly secure the uterus as nearly as possible in its normal anterior position in the safest, surest manner. The recognized methods were: 1st, the operation known as shortening of the round ligaments at the inguinal ring, or the Alexander-Adams operation; 2nd, direct fixation of the uterus forward by stitching it to the anterior abdominal wall or to some anterior portion of the pelvic lining; 3d, shortening of the round ligaments within the abdominal cavity, without destruction of their continuity.

Summary.— From the results of his own operating, he had drawn for his guidance the following rules: —

Be sure the displacement is the cause of the symptoms.

Never resort to operative measures without first exhausting all forms of non-surgical treatment in so far as they may be applicable to the case under consideration.

An adherent backward displacement of the uterus demands for its cure, first, separation of its adhesions; second, anterior fixation.

A backward displacement which is free or has been freed from its adhesions may be secured forward —

First, by shortening of the round ligaments, either by the Alexander-Adams or Wylie method.

Second, by fixation of the uterus to the peritoneum of the anterior abdominal wall, or to that of the anterior pelvic floor (Schücking's method).

The Alexander-Adams method was the only one not involving interference with the peritoneum, and should, he believed, be selected. He made an exception that if, for any other reason, the abdomen had been opened, the Wylie operation might perhaps prove its equal.

DISCUSSION,

DR. F. H. DAVENPORT, of Boston, said that these cases of backward displacement, especially with adhesions, had been looked upon as the *bête noir* of gynæcology and hardly to be remedied at all. The question to-day was not, can this woman be cured? but, by what method shall we cure her? Sänger of Leipsig considered that 20% of the cases of backward displacement were to be operated upon, and were not curable by non-operative measures. He thought those who had practised the method of overcoming the adhesions and replacing the uterus by systematic packing and tamponning the vagina would hardly confess to failure in 20% of the cases.

He agreed with Dr. Strong as to the value of gradual separation of the adhesions in preference to laparotomy. One should not be hopeless too soon about cases in which there were apparently firm adhesions. He had seen such cases yield after months of treatment by tamponning.

DR. E. W. CUSHING, of Boston, said the question of interference in these cases must depend on the social condition of the patient and where she comes from. There seemed to him to be three indications to justify opening the abdomen: 1st, to get the woman out of bed, where she is practically bed-ridden; 2nd, to keep the woman practically out of the poor-house, when she is depending on her own exertions; 3rd, where the woman lives in a place where she can't get treatment.

DR. BURT, of Boston, said that usually, unless there was something, as diseased tubes or ovaries, which needed abdominal incision, he should not feel justified in making an abdominal incision.

DR. H. C. BALDWIN'S paper on

THE NON-RADICAL TREATMENT OF CANCER OF THE UTERUS AND VAGINA

was read by title.

Recent Literature.

The Principles and Practice of Dentistry. By CHAPIN A. HARRIS, M.D., D.D.S. Twelfth edition, revised and edited by Ferdinand J. S. Gorgas, M.D., D.D.S. Philadelphia: P. Blakiston, Son & Co. 1889.

If Chapin A. Harris were to come from his grave and see the child fathered upon him, he would not recognize his own offspring. A diligent search, however, would disclose the "strawberry mark."

This twelfth edition, even more so than its predecessors the tenth and eleventh, is almost a new book, much having been rewritten, much added, and a great deal dropped out as obsolete, superseded by new methods and new discoveries. The book still retains its distinctive form, and as a resumé of the whole science and art of dentistry is now, as it always has been, unlike and unsurpassed by any work of the same character covering similar ground. It is well edited. There is very little of that "padding" which detracts from the value of so many medical, and especially dental, books, the penny-a-line kind of writing, but all is terse and to the point. The volume is an encyclopædia of dentistry, invaluable to the dental student and to the practitioner who has not ceased to be a student.

The various branches of the art are taken up in turn, and quite fully treated, from the anatomy of the mouth and face to the construction of artificial palates. Nothing seems to have been neglected or overlooked. Dental prosthesis, vulgarly called mechanical dentistry, in its new and wonderful development, has received its due share of attention, though we miss the full descriptions of the manufacture of porcelain teeth found in the older editions, become almost obsolete in the dental laboratory, but now, thanks to the cleanly and efficient gas furnaces, being brought to the front again. The value of the book is proved by the numerous editions that have been called for, while the excellence of the editing and the general style of the printing leaves little to be desired.

— The Kansas City *Star* says that "Washburn college is to have a medical department, which will have a tendency to popularize cremation at Topeka."

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 11, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: $5.00 *per year, in advance, postage paid, for the United States and Canada;* $6.00 *per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of The Boston Medical and Surgical Journal, 283 Washington Street, Boston.

283 WASHINGTON STREET, BOSTON, MASS.

DR. BARRY'S REPORT TO THE LOCAL GOVERNMENT BOARD UPON AN EPIDEMIC OF SMALL-POX AT SHEFFIELD, ENGLAND, IN 1887-88.

THIS is one of the most thorough and exhaustive reports upon an epidemic of infectious disease which the Local Government Board of England has yet issued, and contains in its three hundred and four quarto pages a complete history of the scourge from which the city of Sheffield suffered in 1887-88. In the number of the population, the rate of mortality from small-pox, and in some other characteristics, this epidemic bore a marked resemblance to that with which Boston suffered in 1872-73.

The *Sanitary Record* comments on the misrepresentation of this epidemic by those who are wont to decry vaccination, attributing "an outbreak of small-pox in a community so well vaccinated as that of Sheffield as being an evidence of the futility of vaccination. The facts of this epidemic, as now known, constitute one of the most complete vindications of vaccination ever observed."

The report comprises the following topics: a general description of the district; the origin and progress of the epidemic; action of the local authorities; circumstances which influenced the spread of small-pox; and the direct pecuniary cost of the epidemic.

Sheffield is a manufacturing city, having an estimated population (in 1887) of 316,288. The number of reported cases of small-pox for the year ending March 31, 1888, was 6088; the number of deaths from small-pox was 590. The rate of those attacked was therefore 19.3 per 1000 of the population, and the mortality rate from the same cause 1.86. The experience of former epidemics in other localities appears to have been repeated in Sheffield in the fact that hospitals for small-pox in crowded localities play the part of "small-pox distributors."

The report dwells minutely upon the changed incidence of small-pox from childhood to the period beyond the age of ten, and justly attributes the change to vaccination, a "rite," as the opponents of vaccination termed it, which was much more commonly practised since 1872. By a thorough house-to-house visitation it was found that less than 1 per cent. of the school children of Sheffield were unvaccinated, and about 2 per cent. of the people of all ages were unvaccinated. So that, as Dr. Buchanan states in his introduction to Dr. Barry's report, "this 2 per cent. of the population claims to be regarded as so many seventeenth or eighteenth century people scattered about Sheffield for the very purpose of having themselves compared, under nineteenth century conditions of life, with the law-abiding people of the present day."

Comparing the immunity of the vaccinated as compared with the unvaccinated in this epidemic, the rates were as follows: for 100,000 vaccinated children the rate was 9 deaths, and for every 100,000 unvaccinated children the mortality rate was 4,400.

The attack-rate of the vaccinated was 5 per 1000, and of the unvaccinated it was 101.

The vaccinated children had therefore, as compared with the unvaccinated, a twenty-fold immunity from attack, and a four hundred and eighty-fold security against death by small-pox. If the vaccinated children of Sheffield had been attacked at the same rate as the unvaccinated there would have been nearly 7000 attacks among such children instead of the actual 353, and nearly 3000 deaths instead of the actual six. Of the children living in houses actually invaded the attack-rate was 78 per 1000 in the vaccinated, and 869 per 1000 in the unvaccinated, while the death-rate was only 1 per 1000 in the vaccinated, but 381 per 1000 among the unvaccinated. As regards persons over ten years of age, the attack-rate in persons twice vaccinated was 3 per 1000, in persons once vaccinated 19 per 1000, and in persons not vaccinated it was 94 per 1000, whilst the death-rate among those twice vaccinated was 0.08, among those once vaccinated it was 1, and among persons not vaccinated 51.

In the wards and offices of five hospitals there were one hundred and sixty-one persons in attendance on the sick. Of these eighteen had had small-pox before their engagement and none of them became sick; sixty-two persons (nurses) had been vaccinated in infancy only, and of these six were attacked and one died. The remaining eighty-one

persons had been successfully revaccinated and none of them contracted small-pox.

There was also a similar immunity among the vaccinated troops, police force, and post-office officials.

Dr. Barry's report concludes with a statement of the direct cost of the epidemic, and shows that the authorities expended over £32,000 in combating the disease. He also adds: "This expenditure forms but a fraction of the total money loss to the city. Among the losses of which no exact estimate can be formed must be reckoned loss of wages, expense of doctors, maintenance of the sick, cost of funerals, etc. The loss to trade cannot be guessed at. Sheffield was avoided by all outsiders except those whose business was imperative, and even these did not sleep in the town if they could avoid it. The hotels were empty and the people were boycotted by the inhabitants of neighboring towns. In one month (February, 1888) the tramways alone carried 200,000 fewer people than usual."

The report is very abundantly illustrated with maps, tables, and diagrams. In the latter a commendable departure from the stereotyped methods is introduced, and diagrams are presented which appeal at once to the common sense of the intelligent inquirer.

Dr. Barry's report may be commended not only to boards of health as a model of sanitary investigation, but also to all who doubt the efficacy of the recognized measures for the prevention of small-pox.

THE TESTICLE AS A REJUVENATOR.

Twenty years ago, at least, Dr. Brown-Séquard exhibited tendencies towards a belief that the testicle might be of value for other purposes than the impregnation of the ovum, provided it was taken when young, — that it was competent, when its vital principles were properly injected for the respective purposes, not only to call into existence the very young but to rejuvenate the aged.

It seems that this idea has continued to germinate in the brain of the learned, but eccentric, physiologist all these years. In 1875 he made experiments with grafts of testicular tissue upon dogs, and to his delight succeeded, as he thought, in renewing the youth of one wretched old cur. Since then he has continued these strange investigations at various times, and during the month of June this year made two separate communications to the Société de Biologie of Paris upon this subject, describing the methods used and the supposed results. He, apparently, thinks he has discovered a sort of *elixir vitæ*, or fountain of perpetual youth, of simpler composition than those elixirs so sedulously compounded by the mediæval philosophers, and easier of access than the elusive fountain which enticed poor Ponce de Leon to his fond and fatal journey.

According to the reports of Brown-Séquard's communications given by the French journals, he has been experimenting with a fluid obtained by crushing and washing the testicles of young animals, which was mixed with blood from the spermatic veins and water. This fluid he injected into his own subcutaneous cellular tissue almost every day for two weeks, with results so gratifying that he hastened to communicate them to his biological confrères. Notwithstanding his ripe age, between seventy and eighty years, he experienced a rejuvenescence of all his forces, physical and mental. The former healthy and vigorous contractility of the intestines and bladder had returned, as also had his general muscular strength. Intellectual labor had again become easy to him.

Dr. Brown-Séquard did not succeed apparently in inoculating his hearers with his own enthusiasm for his procedure. Scepticism and physiological objections found expression through MM. Dumont-Pallier and Féré. Nor did the society treat his results with sufficient seriousness to discuss the question as to the value of the ovary for similar purposes, or as to the possible results of injecting subcutaneously an ovarian aqueous extract into the male and a testicular extract into the female.

MEDICAL NOTES.

— The city of Ann Arbor, Mich., has voted to issue bonds for $25,000 for the erection of a hospital, for which the legislature appropriated $50,000.

— The death is reported of Prof. Dr. Robert Ultzmann, of Vienna, at the early age of forty-seven years. His book on urinary analysis has been translated into English.

— Dr. Cornet has collected, under the auspices of the German Government, and has collated, statistics showing an alarming frequency of tuberculosis among nurses. His conclusions are published in the Philadelphia *Medical News*, and show that tuberculosis is nine times more frequent among them than among other classes. All infectious diseases also are more frequent among nurses until the fortieth year of life. The statistics therefore clearly demonstrate that the life chances of nurses do not compare favorably with those of other people. Death occurs among them at the average age of about thirty-six years — "an average shorter life

than that of workmen exposed to the inhalation of injurious dust, by eight or ten years."

— At the annual meeting of the New Hampshire Medical Society, held at Concord, June 18, officers were elected as follows: President Dr. William Child, of New Hampton; vice-president, Dr. Lyman B. Howe, of Manchester; secretary, Dr. G. P. Conn, of Concord; treasurer, Dr. D. S. Adams, of Manchester; executive committee, Drs. C. R. Walker, of Concord; G. D. Towne, of Manchester, and J. K. Kimball, of Suncook.

— The South Bend, Ind., *Tribune* gravely states that "a child born recently near Clinton, Ind., and which lived but two hours, was granted before its death the gift of speech long enough to promulgate the following words, which were spoken as plainly and distinctly as a child 6 or 7 years old. It said: 'The present season's crops will be an entire failure, and the succeeding year the world will have reached that long-looked-for and predicted time — the end.' The truth of the above is vouched for by many of the citizens of that section of the country, and the more superstitious predict that it is the forerunner of some great calamity."

— The mental process whereby a medical expert, however honest he may be in original and even in final intention, becomes partisan in his testimony is well described as follows in a late address of Dr. Samuel B. Ward, of Albany, before the Medical Society of the State of New York: —

"The physician selected as an expert considers his case carefully; he reads up the various authorities, paying, of course, considerable attention to those whose views agree with his own, and mentally remarking what sensible men they were, while the impression formed of those who differ from him is not nearly so complimentary. He looks up the records of similar cases in medical journals, and finally goes on the stand well prepared to answer truthfully the questions previously arranged to be asked him on the direct examination. During this investigation of the case it is sometimes curious to observe how the expert's opinions will become strengthened in the direction of the side which he has espoused. Without any real additional arguments having been brought to light he will incline to give more and more weight to facts which seem to favor his view, and become more and more inclined to make light of, or even to ridicule, facts or opinions which militate against him. He often ends by being honestly persuaded that there ought to be no manner of doubt on points which are in reality very doubtful and which at the outset he willingly admitted so to be."

NEW YORK.

— A resolution has been adopted by the board of health directing Dr. Tracy, registrar of vital statistics, to make a daily report of all deaths which occur in tenement houses from pulmonary and intestinal tuberculosis and from tubercular meningitis, and to transmit the same to Dr. Cyrus Edson, chief of the Bureau of Contagious Diseases. Dr. Edson has also been directed to formulate a system of rules for the management of patients in tenement houses suffering from tuberculous diseases.

— Dentists looking out for a place in which to locate would do well to avoid, for the present at least, the 25th ward of Brooklyn. In this district of the city the increase in the population is said to have been quite remarkable during late years; but the number of dentists seems to have increased even more rapidly in proportion, so that competition is now very lively. Two years ago the regulation charge for extracting teeth was one dollar each. Competition compelled a reduction to fifty cents, and this rate was maintained until the 1889 spring graduations of the dental colleges took place, when the price was lowered to fifteen cents per tooth, or two for twenty-five cents.

Miscellany.

SLOW INCREASE OF POPULATION IN FRANCE.

AT a recent session of *La Société d'Anthropologie de Paris* M. Chervin presented a communication upon the slow increase of population in France, considering in detail the various larger geographical regions, and endeavoring by comparison to determine the causes which thus hinder the French in the international world-progress. He gives an interesting mass of facts regarding climate and natality (*natalité*), yet, after all his comparison of data, concludes that the matter has to be undertaken anew, and carried to more particularized detail of study, having the examination of smaller geographical districts in view, before any reasonable origin can be assigned for this comparative decrease of inhabitants. Such an investigation he is disposed to undertake, the results of which he hopes to give to the society.

MAINE REGISTRATION BILL DECIDED NOT TO BE A LAW.

IT will be remembered that on the 17th day of March, 1887, both branches of the Maine legislature passed to be enacted an Act entitled "An Act to Regulate the Practice of Medicine." This Act was signed by the President of the Senate and Speaker of the House on the forenoon of the same day. The Act was then presented to the governor for approval. Gov. Bodwell, soon after receiving the bill, signed it, and it was sent to the secretary of state and placed in the official custody of that offi-

cer as a bill which had become a law. The fact of the governor's approval was entered upon the books kept in the office of the secretary of state known as "Blotter" and "Register." In the afternoon of the same day (the 17th of March) the governor recalled the bill and drew his pen through his signature, and then caused the Act, with his line drawn through his signature, to be sent to the Senate, together with a paper stating his objections thereto. The Senate did not pass it over his objections.

In 1888, Stephen H. Weeks, as president of the Maine Medical Association, in the name of the attorney-general, and by his authority, petitioned the chief justice of the Supreme Court for a writ of mandamus against Oramandel Smith and Charles W. Tilden, the former secretary of state and the latter secretary of the Senate, commanding them to "restore said approved Act, entitled 'An Act to Regulate the Practice of Medicine,' to its place among the Acts of the State in the office of the secretary of state."

The contention of the petitioners was practically that the Act become a law when Gov. Bodwell signed it, and deposited it in the office of the secretary of state, and that his subsequent recall of it and erasure of his signature exceeded his power and did not invalidate the Act. The case was argued for the petitioners by the Hon. C. W. Goddard and Judge J. W. Symonds, and for the secretary of state and deputy secretary of the Senate by Attorney-General Orville D. Baker.

The decision of the court, which is very lengthy, has just been given. It denies the petition and declares that the Act is not a law.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 29, 1889.

Deaths reported 3381; under five years of age 1794; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1055, consumption 331, acute lung diseases 203, diarrhœal diseases 766, diphtheria and croup 147, whooping-cough 32, measles 31, typhoid fever 25, scarlet fever 22, cerebro-spinal meningitis 16, malarial fever 14, erysipelas 3, small-pox (Chicago) one. From measles Cincinnati 13, New York 6, Philadelphia and Brooklyn 5 each, Chicago and Waltham 1 each. From typhoid fever, Philadelphia 5, Baltimore 4, Boston 3, New York, Chicago, Brooklyn and Washington 2 each, St. Louis, Cincinnati, and Newton 1 each. From scarlet fever, New York 7, Chicago and Baltimore 4 each, Philadelphia and Washington 2 each, Brooklyn St. Louis, and Nashville 1 each. From cerebro-spinal meningitis, Cincinnati 4, New York, Chicago, and Washington 3 each, Boston, Nashville, and Quincy 1 each. From malarial fever, Brooklyn 5, New Orleans 3, New York and Baltimore 2 each, Philadelphia and Nashville 1 each. From erysipelas, Chicago 2, Brooklyn 1.

In the 28 greater towns of England and Wales, with an estimated population of 9,555,406, for the week ending June 22nd, the death-rate was 16.7. Deaths reported 3055; infants under one year 757; acute diseases of the respiratory organs (London) 171, measles 115, diarrhœa 105, whooping-cough 76, scarlet fever 47, diphtheria 34, fever 22, small-pox (Manchester) 1.

The death-rates ranged from 9.9 in Brighton to 27.1 in Manchester; Birmingham 16.6; Blackburn 15.5; Hull 25.3; Leeds 21.9, Leicester 15.6; Liverpool 16.9; London 14.9; Nottingham 11.2; Portsmouth 14.0; Sheffield 17.7; Sunderland 18.3.

In Edinburgh 18.0; Glasgow 22.4; Dublin 18.6.

The meteorological record for the week ending June 29, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps: —

Week end'g Saturday, June 29, 1889.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.*			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM JUNE 29, 1889, TO JULY 5, 1889.

The leave of absence for one month granted Major J. K. CORSON, Surgeon, by par. 2, S. O. 65, c. s. Department of the Columbia, is extended one month. Par. 1, S. O. 45, Headquarters Division of the Pacific, June 24, 1889.

Leave of absence for twenty-five days, to commence on or about July 2, 1889, is granted Captain A. R. CHAPIN, Assistant Surgeon, U. S. Army. Par. 6, S. O. 145, Division of the Atlantic, June 27, 1889.

GIBSON, R. J., Captain and Assistant Surgeon, U. S. Army, reports arrival July 2, 1889, at Camp Lewis, Fisher's Island, N. Y., in compliance with par. 5, S. O. 133, Division of the Atlantic, which designated him as M. O. for the encampment (rifle practice) at Fisher's Island, N. Y.

By direction of the Secretary of War, leave of absence for two months is granted Captain GEORGE T. BEALE, medical storekeeper. Par. 8, S. O. 148, A. G. O., June 27, 1889.

BOOKS AND PAMPHLETS RECEIVED.

The Physicians' Leisure Library. The Treatment of the Morphia Disease. By Erlenmeyer. Translated by E. P. Hurd, M.D. 1888.

Ueber Ichthyol-Behandlung des Erysipelas. Von Dr. Von Brunn (Lippspringe). Sonder-Abdruck. Berlin. Heft No. 5. Mai, 1889.

Beobachtungen über das Ichthyol nach dreijähriger Anwendung. Von Dr. von Hoffmann, Dirigent der Augenheilanstalt, und Dr. Lange, pract. Arzt, in Baden-Baden. Sonder-Abdruck. Berlin. Heft No. 5. Mai, 1889.

Aus dem Russischen der Moskauer Medicinischen Rundschau. Von DDr. A. Buljeff, W. N. Sorokin, S. Preobrashensky, W. L. Shadkewitsch, J. Jelin. Separat-Abdruck. Berlin. 1889.

De la Lobéline dans la Thérapeutique de L'Asthme. Mémoire présenté au 1er Congrès Brésilien de Médecine et Chirurgie, et lu, devant le même Congrès, à la Séance du 15 Septembre, 1888. Par le Dr Silva Nunes. Rio de Janeiro. 1889.

Papers read before the Medico-Legal Society of New York. From its organization. First series. Third illustrated edition. New York. New York Medico-Legal Association. 1889.

An Essay on Asphyxia (Apnœa). By George Johnson, M.D. F.R.C.P., etc. London: J. & A. Churchill. 1889.

Thirteenth Annual Report of the Sea-Shore Home for the Summer of 1888. Boston. 1889.

Medical and Surgical Reports of the City Hospital of the City of Boston. Fourth Series. Boston. 1889.

A Contribution to the study of Friedreich's Ataxia. With Exhibition of Cases. By J. P. Crosier Griffith, M.D., etc. Reprint.

The Old Hospital, and other Papers. By D. B. St. John Roosa, M.D., LL.D. Second revised and enlarged edition of "A Doctor's Suggestions." New York: William Wood & Co. 1889.

Morrow's Atlas of Venereal and Skin Diseases. William Wood & Co., New York. 1889. Nos. 14 and 15.

Transactions of the Medical Society of the State of New York for the year 1889. Published by the Society. 1889.

Transactions of the American Orthopædic Association. Vol. 1. Published by the Association. 1889.

Darwinism: an Exposition of the Theory of Natural Selection, with some of its applications. By Alfred Russel Wallace, LL.D., F.L.S., etc. With map and illustrations. London: Macmillan & Co.; and New York. 1889.

Pathological Report, 1887-88, of the City of London Hospital for Diseases of the Chest, Victoria Park, E. By Sidney Martin, M.D. (Lond.), Assistant Physician to the Hospital, late Pathologist and Registrar. Printed for the Victoria Park Hospital. 1889.

A System of Obstetrics by American Authors. Edited by Barton Cooke Hirst, M.D., associate Professor of Obstetrics in the University of Pennsylvania, etc. Volume II. Illustrated with 221 engravings on wood. Philadelphia: Lea Brothers & Co. 1889.

Synopsis of Human Anatomy, being a complete compend for Anatomy, including the anatomy of the viscera, and numerous tables. By James K. Young, M.D., Instructor in Orthopedic Surgery etc., in the University of Pennsylvania. Philadelphia: F. A. Davis Publisher. 1889.

Maladies de la Langue. Par le Dr. Henry T. Butlin, Chirurgien assistant et professeur de Chirurgie pratique et de Laryngologie à Saint-Barthalomew's Hospital. Traduit de l'Anglais par le Dr. Douglas Aigre, ancien interne des Hôpitaux de Paris. Paris: Aux Bureaux du Progrès Médical, 14 Rue des Carmes. 1889.

Manuel Pratique de la Garde-Malade et de L'Infirmière. Publié par le Dr. Bourneville, Médecin de Bicêtre, Directeur des Ecoles municipales d'Infirmières. Avec la collaboration de MM. Blondeau, de Boyer, Ed. Brissaud, Budin, P. Kéraval, G. Manoury Monod, Poirier, Ch. H. Petit-Vendol, Pinon, P. Regnard, Sevestre, Sollier, et P. Yvon. La 4me édition revue et augmentée. Tome i.: Anatomie et Physiologie. Tome ii.: Administration et comptabilité hospitalière. Tome iii.: Pansements. Tome iv.: Femmes en couches; Soins à donner aux aliénés; Médicaments. Petit Dictionnaire. Tome v.: Hygiène. Paris: Aux Bureaux du Progrès Médical, 14 Rue des Carmes, Paris. 1889.

CLINICAL OBSERVATIONS IN AURAL PRACTICE.[1]

BY J. ORNE GREEN, M.D.,
Clinical Professor of Otology in Harvard University.

MALIGNANT DISEASE OF THE EAR.

CASE I. A woman, aged fifty-eight, was taken with pain in the left ear in the summer of 1887, which was soon followed by otorrhœa, and the whole history was at first the common one of purulent inflammation of the tympanum with perforation of the drum-membrane. No systematic treatment was followed, and the otorrhœa continued with occasional but slight pain. In the autumn the pain increased, the ear became sensitive on lying upon it, and in November slight œdema appeared, both in front, below, and behind the auricle, and paralysis of the facial nerve in all its branches occurred.

I saw her then for the first time, and found very marked œdema over the mastoid and a sensitive bone; slight œdema below and in front of the auricle, with slight redness of the skin. There was no fluctuation. The meatus was full of very thin muco-purulent matter, and, after cleansing, was found filled with exuberant granulations which concealed the deeper parts. The meatus was exquisitely sensitive, so that thorough exploration with the probe was impossible. The pain for a week or two had been very severe, and there was moderate fever, with a weak and slightly irregular pulse, by which the patient had been much reduced. The facial paralysis included all branches of the nerve and was almost complete. There was no family history to arouse suspicion. The deafness was total in that ear.

From the œdema and tenderness of the mastoid, the obstructions in the meatus, and the great pain, I advised an immediate opening of the mastoid and a thorough clearing out of the meatus to insure perfect cleansing and drainage. A few days after, the operation was done at the Massachusetts General Hospital. No pus was found beneath the periosteum, and after exposure of the bone the mastoid cells were opened in their extreme upper part with the gouge and hammer, the cortex of the bone being a little over one-eighth of an inch in thickness. The granulations in the meatus were removed by the snare, and the probe then detected a caries involving the whole tympanum and the deeper parts of the osseous meatus. With curved aural curettes in the meatus as much of this carious bone was removed as possible, and a free communication was established between the mastoid opening and the tympanum and meatus. A drainage-tube was inserted in the mastoid, the whole douched daily with carbolic solution, 1 : 60, and kept under an aseptic dressing. For three or four weeks the pain was greatly relieved and the fever disappeared entirely, but it was found that the caries was extending andseveral minute bits of necrosed cancellated structure were removed from the mastoid.

The subsequent history extends over a period of eight months: the pain gradually returned, of a dull grinding character, in the ear and over that side of the head; the discharge, never thoroughly purulent, became more sanious and offensive in spite of cleansing twice a day, and the bone very slowly disappeared in the discharge without any sequestra forming. At the end of four months the edges of the wound began to break down, and soon after exuberant granulations appeared on the anterior lip of the wound. These slowly increased till they reached a size of three inches in length, two in breadth, and two in thickness; at first smooth, they gradually became somewhat nodulated, and masses sloughed away frequently; in two or three spots they broke down, forming new openings into the mastoid cavity. Whenever examined with the probe the bone was felt to be very friable, the instrument being readily pushed directly into its structure. During the last two months the pain was frequently lancinating and referred chiefly to the region of the ear. Although complaint was made of the neck and left shoulder, no enlarged glands were ever discovered, or any cause for the pain in those regions.

About nine months after the operation, and fourteen months from the beginning of the aural disease, the patient died from exhaustion, which had steadily but almost imperceptibly been increasing for several months.

No microscopical examination was made at any time, for the extreme sensitiveness of the growth forbade any attempt to remove any portions of it.

CASE II. A man, aged fifty-seven, of good family history, had suffered three years before from "nervous prostration," from which he had partially recovered. Early in the spring of 1888, from a cold, as he said, he had severe pain in the right ear, which lasted some days but passed away without otorrhœa. In April, a few weeks after this first attack, there was a recurrence of pain, with discharge, and in May a small growth was removed, as was said, from the floor of the meatus. The pain greatly increased after this, the discharge continued, and in July another growth, resembling a polypus, was removed from the meatus, although from what part could not be ascertained.

In August, when I first saw him, he was in an extremely nervous state, the pain was continuous and severe in the ear, and there was a temperature of 102° and a pulse of 120. Close to the auricle, both below and behind, there was great œdema of the skin but not marked tenderness of the mastoid bone. There was distinct fluctuation below the auricle, between the mastoid and lower jaw. The meatus was filled with fleshy masses which completely closed the passages and was exuding an abundant muco-sanious secretion. All of the inflamed parts were exquisitely sensitive to the touch. A minute drainage-tube was worked into the meatus, and immediately on reaching the deeper parts gave exit to a considerable amount of secretion, and pressure on the fluctuating swelling below brought out much more discharge, showing a free communication, and that this swelling was a gravitation abscess from the ear. A small rubber drainage-tube was kept in the meatus, through which the abscess was evacuated twice a day, and the whole ear cleansed by carbolic solution. After a few days of this treatment the febrile reaction entirely subsided and there was less pain; by in-

[1] Read before the Boston Society for Medical Observation, March 4, 1889.

spection and by the probe, however, it was found that the whole osseous meatus and tympanum were denuded and carious. The external œdema diminished but did not disappear.

The patient was kept under observation for about two weeks and then returned home to have systematic cleansing and drainage carried out till either a sequestrum should form which could be removed, or further developments occur. One symptom strongly roused my suspicions during the period in which I had him under observation: this was a slow but constant melting away of the soft structures of the meatus, so that when he left the edges of the ulceration had extended from the osseous meatus nearly to the auricle.

The subsequent history is brief. In my absence Dr. George W. Leland was called to see him, and furnishes the remaining history. He found the meatus again filled with flesh-like growths and the gravitation abscess so filled that it was opened; the caries still existed. The removal of the growths and opening of the abscess gave much relief to the pain. Examination of the urine showed desquamative nephritis. Complete paralysis of the right facial existed at this time, and the tissues at the seat of incision showed a yellowish infiltration. Dr. W. W. Gannett reported as follows on the growth which was removed: "It showed a superficial layer of many-layered flat epithelium, in which, and extending below, were hairs in hair-follicles. The underlying tissue, composing all the rest of the part removed, was made up of small round cells embedded in a stroma of connective tissue. There was no uniformity in the stroma, the amount of fibrous tissue in parts being small, in other parts abundant and in bundles; the distribution of the fibres was irregular. In the tissue were several small arteries.

"We have to do here with a tissue belonging to the connective tissue series. So far as the microscopic examination goes it might be simply a chronic inflammatory connective tissue. Again, it may form part of a sarcoma. The distinction between the two can only be made by determining the size of the remaining portion. If considerable it is a sarcoma; if slight it is probably of inflammatory origin.

"So far as the evidence to be derived from the small bit is concerned, it is rather more in favor of an inflammatory product than a sarcoma."

Ten days after, Dr. Leland found that the cavity at the bottom of the canal was much enlarged, the walls having disintegrated. There was no return of pain or of new growths.

Some ten days later the cavity of the middle ear had become very much larger, but no sequestrum could be found. Weakness was increasing, and œdema and ascites showed themselves. Three weeks after this he died from exhaustion, without new symptoms, about seven months after the beginning of the ear-disease.

After death, the nurse reported that a mass of cotton as large as her fist was required to fill the meatus, showing that a very large cavity had been excavated by the disease.

CASE III. A woman aged thirty-one passed into my hands upon going on duty at the Massachusetts Eye and Ear Infirmary on November 1. She was a stout, well-nourished woman, in whom an otorrhœa on the left side had existed from three years of age, undoubtedly a chronic, purulent inflammation of the tympanum. The summer before she had applied at the infirmary for acute mastoid inflammation, and a subperiosteal abscess was incised by Dr. Jack. The wound never healed, and in September, as it was found that there was a fistula through the bone and caries within the mastoid, a second operation was done by Dr. Jack and the carious bone curetted.

When I first saw her there were two small openings in the skin over the mastoid, and the meatus was closed by a general swelling, not œdematous, of all its walls. There was an abundant sanious discharge from the mastoid openings and from the meatus. The left cheek was much swollen and œdematous. A probe showed that nearly the whole of the petrous portion of the temporal bone had disappeared; the probe passed directly inwards from the mastoid opening for fully two inches, and forwards and inwards for fully three inches, without any bone being felt; backwards the edges of the carious bone could be felt. Deep pressure showed a circular depression over the malar bone three-fourths of an inch in diameter and at the same time forced secretion from the meatus, showing a communication with the ear.

There was scarcely any pain except after manipulations of the inflamed parts. Injections passed freely from the meatus out of the mastoid openings.

Some days after, slight chills, fever, pain in the ear, and complaint of weakness showed themselves, but passed away in a few days under careful evacuation and cleansing of the diseased cavity. A firm swelling then appeared close to the auricle below and behind, not painful and not sensitive. This increased in size, broke down in two spots behind the auricle, and the edges of the openings became rapidly irregular. In the course of two weeks this swelling extended from the lobule backwards for one inch, upwards for one inch, and forwards for another inch, and showed distinct nodules, four or five in number. No enlarged glands could be discovered. The deafness on that side was total. Despairing of relief the patient left for home. Two months after she was seen by one of the attendants of the infirmary, who reported that the tumor had more than doubled in size. She died February 28th.

The diagnosis of malignant disease in all of these cases was made from the clinical history. I regret extremely that in none of them was it possible to make any microscopic examinations, and especially that it was not possible to get a thorough examination of the petrous bones to decide on the pathological variety of the disease and its place of origin.

Notwithstanding, however, the lack of microscopical confirmation of the diagnosis, in Cases I. and III., the development of the external tumors late in the disease goes very far to confirm my opinion of its malignant nature, these growths presenting all of the macroscopical characters of malignancy in rapid growth, nodulation, and rapid breaking down. The second case, it is true, did not develop any growth externally; but the rapid

ulceration of the soft structures of the meatus without any apparent cause, such as pressure or retention of pus, certainly suggests malignant disease. This patient, it will be noticed, died much earlier in the disease than the others, and never reached the extensive destruction of the bone which was found in both the other cases and which in both preceded the external growths.

All three cases were peculiar in their course, and were early recognized as different from the ordinary cases of caries. It is not easy to define all of these little peculiarities. The characteristic which particularly struck me was the rapid and extensive destruction of the bone by complete disintegration without the formation of any sequestra, and this in a bone containing a large amount of cancellated structure, which usually separates very readily when inflamed for any length of time.

Whether the original disease was malignant in Cases I. and II., or whether the malignancy was a subsequent development upon a simple purulent inflammation of the tympanum, must remain undecided. In Case III., however, there can be no doubt that the malignancy was of recent origin, as the otorrhœa had existed for twenty-four years.

In connection with these cases I show a drawing of a round-celled sarcoma of the ear, the case having been published in the *Archives of Otology* in 1884. In this case also the malignant disease developed upon a purulent inflammation of the tympanum of seventeen years' duration. The drawing was taken some two months before death; the growth afterwards increased enormously, and at death was nearly half as large as the patient's head.

All of the three cases reported offer demonstrations of the difficulty of diagnosticating malignant disease within the tympanum or bone in its earlier stages; and now, in putting together and reviewing them, I see nothing except the clinical history, as the case proceeds, which can give us a clue to the true malignant nature of the process. The character of the discharge, the exquisite sensitiveness in two of the three cases, the extensive and general infiltration of the tissues about the meatus and the mastoid, might all of them arouse suspicions, but none of them are conclusive evidence of malignancy. Finally, I do not myself believe that microscopical examination of the growths from the meatus would be at all satisfactory, for I have no doubt that many, if not all, of these are simple inflammatory granulation-tissue, and do not represent the disease, which I believe is seated in the bone itself.

PAROTID TUMORS DUE TO INFLAMMATION OF THE TYMPANUM.

Case I. A man aged forty-seven applied to me for deafness and an otorrhœa of two years' duration and facial paralysis of two months' duration. The facial paralysis was preceded by pain in the ear of three days' duration, and had gradually increased till it was almost complete. Just in front of the auricle was a firm, oval, freely movable tumor of the size of a filbert, which the patient said appeared quite suddenly soon after the pain in the ear and with the facial paralysis. It was painless and not sensitive on pressure. So fully was he impressed with the idea that the paralysis and the tumor were connected that I advised his seeing another surgeon, who pronounced the tumor a parotid tumor and independent both of the paralysis and the ear-disease.

Examination of the ear showed a purulent inflammation of the tympanum, with a loss of the lower half of the drum-membrane and very great swelling of the mucous membrane over the promontory. Two or three applications to the tympanic cavity by means of the tympanic syringe reduced the swelling, and it was then found that the edge of the promontory, over a surface somewhat larger than a pin's head, was carious. This was cleaned off by a minute curette and treated by iodoform. At the end of six weeks the tympanic inflammation had subsided, the bone had healed, and there was no discharge. The tumor, which had remained throughout the treatment just as when first seen, within five days after the cessation of the tympanic discharge disappeared and never returned, although one year afterwards, accompanying the development of a disease of the lungs, probably phthisical, there was a slight attack of inflammation of the same tympanum.

The facial paralysis gradually improved, and at the end of a year no deformity of the face was visible, although it was impossible for him to whistle and there was still a feeling of numbness.

This was the first case in which my attention was called to a possible connection between some of these tumors and the ear. I was able afterwards to recall two or three instances where patients had consulted me about similar tumors, when I saw them with reference to ear-disease, but I had always pronounced the tumors independent of the ear.

Case II. Some two years after the above observation, a man aged about twenty-five appeared at the City Hospital with a profuse, offensive, chronic suppuration of the tympanum of several years' duration. About a quarter of an inch in front of the tragus was a firm oval tumor, freely movable, about the size of an almond, which he said had existed for three months only. It was exactly similar in character to the first, above described, being smooth, painless, insensitive, without redness or fluctuation.

The ear was treated by antiseptic cleansing and by applications to the tympanum, and within two weeks, as the offensive odor and the amount of discharge diminished, the tumor entirely disappeared. Unfortunately the patient ceased attendance as soon as somewhat relieved, and I know nothing further of the case.

Case III. A man aged fifty-seven applied to me on account of deafness and a parotid tumor which he associated together. This was some months after the last case.

The history was one of pain in the left ear about a year before, followed by discharge which continued for some weeks, since which time there had been some deafness and subjective noises. During the discharge from the ear the parotid tumor had developed, and had since remained without change and without symptoms.

Examination of the ear showed a drum-membrane thickened, retracted, and with a healed perforation in its posterior segment, the appearances undoubt-

edly due to a purulent inflammation of the tympanum at the time of his pain and otorrhœa. In the same spot as in the preceding cases was a tumor the size of a hazel-nut, presenting the same characteristics already described in the other cases.

As the ear in its present condition offered no signs of irritation, and as no change in the tumor had followed the healing of the ear months before, I could only advise the removal of the growth. His intelligent and positive account of the development of the growth at the time of the ear-disease, with my experience in the other two cases, led me to think that in this case we had to deal with a permanent hyperplasia which could only be gotten rid of by removal.

My presumption is that in all of these cases I had to deal with an enlarged lymph-gland in direct connection with the tympanum, although, as far as I know, anatomy has not, as yet, demonstrated this connection. The relief of the tympanic inflammation apparently removed the source of the glandular irritation and allowed the swollen gland to resume its normal condition. The cases are too few to prove this conclusively; but I have thought it worth while to direct attention to them in the hope that further observations may be directed to the possible connection between some, at least, of these small parotid tumors and tympanic suppurations.

Occasionally, during the last few years, I have found, with suppurations of the tympanum, a decidedly tender spot in the exact situation in which these tumors lie, but without any swelling being appreciable. This, I think, is probably due to a slight irritation of the same gland, not enough, however, to produce a perceptible enlargement. The glands which are usually enlarged with tympanic suppuration are those below the auricle, along the anterior edge of the sterno-cleido-mastoid muscle.

A CASE OF TUBERCULOSIS OF THE PERICARDIUM AND BRONCHIAL LYMPH GLANDS.

BY CHARLES C. TOWER, M.D., SOUTH WEYMOUTH.

MR. C. S. F. was a native of Canada, and for forty-eight years a resident of Weymouth, Mass. He was sixty-seven years of age, married, of Anglo-Saxon race, light complexion, florid countenance, and nervous temperament. He was six feet in stature, erect in figure, and his average weight was one hundred and eighty-five pounds. He followed the occupation of bootmaker up to fourteen years ago, when, his health being poor, he left the shop and the boot business, and became a man of all work, chiefly farmer.

On his mother's side his family history was consumptive, his mother and four maternal aunts having died of phthisis. Two sisters also died of this disease. All of these relatives died in the twenties or thirties. Of two brothers whose death preceded his, neither died of consumption, the age of one being forty, and that of the other unknown. One brother and one sister still survive him, the former in his seventy-third year, and the latter in her sixtieth, and both in good health. On the father's side there is no consumption.

Mr. F.'s general state of health was considered to be fairly good. He usually ate and slept well, and he was strong and free from indications of constitutional disease, except that when a young man of twenty he had, on his own statement, a bad cough attended with loss of appetite and strength, and was regarded by his friends to be in consumption. During my acquaintance with him, extending over a period of twenty-nine years, I recall attendance upon him for several ailments, which go to show that his health was not what may be termed vigorous. Some eighteen years ago he complained of a feeling of weakness and discomfort in the left hypochondrium, which lasted for a period of two or three years, and which on examination of the case appeared to be a muscular strain, the result of heavy lifting. He was also subject to gastric disorders, and suffered considerably from palpitation. The heart was repeatedly examined, but no organic disease detected, although there was observed an occasional intermittency of the pulse, which manifested itself throughout the remainder of his life. He was also troubled for a considerable period with fissure of the rectum, which finally healed of itself.

In 1876 he was confined to bed a couple of weeks with an attack of epididymitis following the mumps. Atrophy of the testicle supervened. At a later period he had rheumatic inflammation of the shoulder-joint, which lasted over a year. Early in November, 1887, after sitting during religious services in a warm church and then going into a cool vestry, he was seized with a fainting fit, and was not restored to consciousness for nearly an hour.

The last illness was developed after special exposure on Christmas night, a year ago. The attack commenced with hoarseness, succeeded later by cough, and the symptoms of acute bronchitis, for which in the latter part of January I was called in. Nothing peculiar in the nature of the cough impressed itself on my memory. The patient, at this my first visit, was about house, and even attending to his out-of-doors duties. I saw him a week later, when he was obliged to take to bed on account of an attack of acute rheumatism, which lasted throughout the month of February, and continued somewhat into March. This attack was manifested by the usual symptoms of the disease, viz., fever, swelling and pain of joints, copious perspiration, and the uric acid diathesis, and it was treated in the usual manner. The cough, however, showed no abatement but still continued, and demanded treatment for the comfort of the patient.

In April the condition was one of marked debility. Night sweats at this period were quite pronounced. The cough was harassing, disturbing the sleep by night and exhausting his strength by day. The pulse was weak and considerably accelerated, and the temperature elevated two to three degrees, especially towards evening. The action of the heart was at this time very feeble, and there seemed to be more prostration of the system than could be accounted for by his sickness, although the alkaline treatment employed to eliminate the uric acid from his system had undoubtedly in a measure impoverished the blood, as shown by the marked pallor of the surface of the body, and by the clammy state of the skin. But the most discouraging feature of the case was the persistency of the

cough, which was dry and paroxysmal, and the cause of which I had failed to demonstrate to my entire satisfaction, although it appeared to be due to reflex irritation. The seat of this irritation was referred by the patient to the larynx, and he began at this time to complain of a feeling of distress, referred to the sternal and cardiac region. Repeated careful stethoscopic examinations of the thorax failed to reveal serious disease of lungs or heart. There was good resonance on percussion over both lungs, and the respiratory murmur was clear and full, except as modified by a few muco-crepitant râles, which were most noticeable towards the base of right lung. The cardiac dulness was normal, and the heart-sounds not unusual in character, except feeble and distant, with possibly an occasional souffle, which condition was attributed to the rheumatic attack. The pharynx at this stage of the disease presented nothing remarkable, possibly slight congestion.

There being no improvement in the character of the symptoms during the next three weeks, the desire was expressed by the patient to enter the Massachusetts General Hospital for examination and treatment.

Arrangements having been made for the occupancy of a private room, he entered the hospital May 17. A statement of his condition, as copied in the case-book from a letter written by myself, was that it was one of debility, as indicated by failure in appetite, night sweats, loss in weight, and slight elevation in temperature. The most troublesome symptom was cough, which was described as spasmodic, and attended with very little expectoration. The record further says, "The patient complains of a tickling sensation in throat, which is excited by a deep inspiration or by speaking loud. Cannot lie on right side because of pain in front of right chest when in that position. Has dull, heavy pain in sternal region. Says when he swallows "the food causes pain all the way down to the stomach." Has to pass urine frequently. Appetite poor. Bowels regular. Examination: — Large man, somewhat emaciated. Tongue moist, clean. Examination of throat and nares by Dr. Langmaid shows nothing abnormal whatever. Good resonance over both lungs. Respiration everywhere vesicular. Over lower right back and axillary region a very few medium and fine moist râles. Heart apex in normal position. Sounds clear, but rather feeble. Abdomen normal. Pulse weak and soft.

May 18. Urine normal, acid; specific gravity, 1018. No albumen. Sediment contains considerable urates.

May 19. Patient is quite comfortable when up about the wards, but on lying down cough is troublesome. Complains of soreness in epigastrium and sternal region.

May 21. Has very little trouble from cough, but was nauseated for a time.

May 22. Appetite poor. Complains of pain and soreness across upper part of abdomen and in sternal region.

May 23. Patient discharged at his own request.

From this date the case went on with very little change in respect of the cough and the præcordial distress, except that as the weeks went by and the warm weather came on he took more exercise in the open air and his general condition somewhat improved. The night sweats entirely disappeared in the month of July, and his appetite and strength in a measure returned. The cough, however, did not improve, but on the other hand was more and more aggravated by the dorsal position, compelling him to lie with the shoulders considerably elevated. At this time he rode out daily and took short walks in the open air, so that his countenance became more natural in color. It was, however, always clear and fresh looking, and did not present a cachectic look.

In August the case was allowed to take its course to a large extent independent of drug treatment, until in the latter part of the month it came under the management of Dr. F. F. Forsaith, of Weymouth. He first saw and examined the patient at his office after he had taken a morning ride of three miles from his home. "He gave signs at that time," according to Dr. F.'s statement, "of great weakness, and was hardly able to support himself. He was very much emaciated, and presented the appearance of having within a recent period grown prematurely old. His appetite was reported as poor, and his digestion not good. He was a little constipated. There was present an incessant, harrowing cough.

Examination: — The area of dulness over hepatic region considerably enlarged, indicating an engorgement or hypertrophy of liver. The tongue was somewhat coated, especially at the base. There was no jaundice observed. The lungs on percussion were pretty clear. There was an area some two by three inches in extent, situated just to the right of the sternum and opposite the cartilages of second and third ribs, which was unusually resonant. There was no fullness in that location at that time, but at a later period the right anterior and middle portion of chest became unusually prominent. The lungs were pretty free from râles. They were more noticeable over region of right lung than left, and increased from apex towards base. While there was no sign of valvular disease of heart, its action was feeble and unsatisfactory. There was no increased area of cardiac dulness, and no displacement of that organ.

After a few weeks dulness was apparent at lower part of thorax on both sides, and the stethoscope showed a deficiency of the respiratory murmur, giving the idea of an accumulation of fluid. Early in September a soft swelling began to show itself over upper part of sternum, extending across that bone to the front of right chest in the location previously observed to be hyper-resonant. This tumor gradually increased in size, was painless, and to the touch appeared to contain fluid. Dr. F. is not aware that there was at any time any unusual cardiac dulness, neither was there any evidence of disease of the lung tissue. The temperature ranged from 101° to 103° and did not indicate imflammatory action. There was no evidence of the existence of rheumatism while under his observation, but some little trouble in urination was noted. The patient when first seen by him could lie down flat, but the cough was increased by so doing. As the case progressed he was obliged to have his shoulders more and more elevated in bed. Œdema of the feet and legs was noticed early in October, and continued till the close of life.

The case came into my hands a second time in the latter part of October, when Dr. Forsaith met me in consultation. The œdema had considerably increased, and marked dulness existed over base of thorax behind. The pulse was very small and weak, and from 90 to 100 in frequency. The respiration was also considerably accelerated. The position taken while in bed was bolt upright, and towards the last a support was placed in front for him to lean forward and rest his head upon. Any attempt at this time to lie on his back produced increased distress and aggravated the cough. The tumor already described as occupying the upper part of sternum and right front of thorax continued in much the same condition. There was good resonance over it, and the respiratory sounds were distinctly heard through it. Consequently there was no indication of the existence of aneurism.

About the 1st of November the patient was seen by Dr. W. C. B. Fifield, who aspirated the tumor with a small trocar. The fluid withdrawn was of the nature of bloody serum, and under the microscope showed no cancer cells. The case was, however, regarded as one of malignant disease, and no further treatment was advised.

Death occurred November 22, 1888, the mind remaining clear almost to the last.

At the autopsy, performed on November 23, the external tumor was found to contain about two fluid ounces of thick pus, which lay between the integument and the periosteum of the manubrium, burrowing between the cartilages of the first and second ribs of right thorax, and extending on under side of sternum about half-way across, but nowhere laying bare the bone. The abscess wall was adherent to the apex of right lung, but did not penetrate its substance. The upper lobe of left lung was friable and easily torn in separating the pleuritic adhesions to wall of thorax. The interior mediastinum, the pericardium, heart, pleuræ, and all the tissues underlying the sternum were involved in one mass of disease, and were sent to Prof. Fitz for examination.

Dr. R. H. Fitz reported, in regard to autopsy, that the pericardial cavity was obliterated by firm adhesions. Numerous cheesy plates and nodules, the largest perhaps three-fourths of an inch in the largest diameter and one-fifth of an inch in thickness, were found intimately connected with the parietal and visceral layers. Those of the substernal layer were continuous with similar nodules in the anterior mediastinum, the tissues of which were generally thickened. Small gray and opaque granules were also found in the pericardium.

The lymph-glands at the tracheal bifurcation formed a solid mass nearly as large as the fist. On section these glands were enlarged and cheesy, often softened into curd-like material.

The appearances were characteristic of a chronic tuberculosis of the pericardium and bronchial lymphatic glands. The former was probably the result of the latter, and had apparently extended to the tissues of the anterior mediastinum.

— The Amoskeag corporation of Manchester, N. H., has lately authorized the vaccination of its 8000 operatives at its own expense.

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.[1]

BY E. H. BRADFORD, M.D., AND E. G. BRACKETT, M.D.

PARALYTIC DEFORMITY OF THE FOOT.

Fisher[22] has given a very full and able description of the paralytic deformities of the foot, and has classified them with reference to the degree of distortion in such a way as to emphasize the mode of occurrence.

Talipes arcuatus.—The description of this very closely applies to Schaffer's non-deforming club-foot, the abnormal condition consisting in an increase in the height of the arch. This he considers results during the period of slight paralysis, as after scarlet fever, from the slight contraction of the plantar fascia; that later, as growth proceeds, there is a want of proper accommodation of the contracted parts, and an arching is thus brought about.

An aggravated condition of arcuatus constitutes a *talipes plantaris*, and this forms a link to equinus. The etiological conditions are the same as in arcuatus, but more severe, the extensors of the toes and tibialis anticus being particularly affected. In addition to the arching, the anterior part of the foot is depressed below its normal level, and bands of contracted tissue are found to draw this portion downward and backward.

Of *talipes equinus* three forms are described. The first results from a muscular condition similar to that in *plantaris*, and consists of a bending of the part of the foot anterior to the os calcis at a sharp angle. The distortion is maintained by the shortened condition of the ligaments of the sole and the short flexor muscles. Owing to the downward and backward dislocation of the cuboid and scaphoid bones, the head of the astragalus projects on the dorsum. Another, but less common form, more nearly resembles the spastic equinus, and consists of a flexion of the whole foot at the ankle-joint. Besides these two, a combination is sometimes met with and consists of a flexion of the foot with also a depression of the anterior portion, due to the imperfect action of muscles of this part. In some cases this condition becomes extreme. In the treatment of this combined form the shape of the foot should first be restored, and, later, tenotomy of the tendo Achillis.

The *varus* varieties he describes as the result of a paralysis affecting the extensors of the toes, but in which the tibialis anticus retains its integrity in whole or in part. The first degree of this deformity closely resembles a slight equinus, but in this the depression of the fore-foot is accompanied by slight inversion. With still greater deformity there is more marked contraction of the sole, and the front of the foot is rotated as well as inverted; only the outer metatarsals touch the ground, and the inner border of the foot is so raised that the great and second toes touch only on their tips. The heel is somewhat raised, and this deformity, in this respect as well as in the contraction of the sole, resembles some forms of equinus.

The next stage of this paralytic deformity resembles the usual form of equinus varus. There is rota-

[1] Concluded from page 37.
[22] Lancet, 1889, i. 112, 165, and 214.

tion at the ankle and transverse tarsal joints, and also a considerable amount of inversion. The bearing surface is on the outer border of the foot only, and there is a sulcus running antero-posteriorly along the front part of the sole, showing that the metatarsal bones are abnormally close. The heel is raised, and the toes are drawn upward and are claw-shaped. The deformity shows that a distortion resulting from an infantile paralysis may have the characteristics of the congenital form. Later in life aggravated conditions of the above are met with. For treatment he states: "The reduction of deformity in a case of advanced paralytic varus must be proceeded with in three stages: First, the inversion of the foot upon the leg must be removed; next, the distortion of the foot itself must be proceeded with; finally, having brought the case to one of simple equinus, with elevation of the heel, the usual course of treatment for such a condition is followed."

Another form of the paralytic varus is due to "right-angled contraction of the tendo Achillis." When raised from the ground there is merely a "state of flaccid extension, with slight contraction of the sole." When, however, the weight is borne on the foot, the heel is elevated; the foot is inverted and rotated so that the anterior part of the outer border is alone in contact with the ground." In these cases there is always marked paresis of the extensors of the toes and the peronei. In the act of walking the lateral displacement compensates for the want of flexion, and the use of the limb with the foot in this position tends to increase the deformity.

Of the *valgus* three varieties are described: One is due to a "right-angled contraction of the tendo Achillis," as in varus. The distortion is produced by standing on the foot, the loss of flexion being compensated by the rotation and eversion, which is brought about by the stronger action of the everting muscles.

A second variety results from a slight shortening of the tendo Achillis, and closely resembles "splay foot." There has been slight impairment of the anterior muscles, and the extensors have remained permanently shortened. The limited flexion at the ankle-joint is attended by an abnormal amount of motion at the medio-tarsal joint, which becomes weakened by the constant strain.

The third variety consists of a simple eversion of the foot on the leg, resulting from paralysis of the tibialis anticus and posticus. A light degree of this deformity, due to weakness of the inverting muscles, is frequently seen in children, but severe grades seldom occur before twelve or fourteen years.

The *calcaneus* is very seldom seen, and produces the least disability. "The muscular disturbance which precedes the development of this distortion consists in great loss of contractile power of the posterior muscles of the leg, with only slight weakening of the flexors (extensors?) of the foot. The power of extending the foot is extremely feeble or is altogether wanting, so that the heel becomes considerably depressed; the anterior muscles by their over-action increase the depression of the heel, and also distort the foot itself by drawing up that portion of it in front of the transverse tarsal joint." The plantar fascia becomes contracted and adds to the deformity. The treatment is not very satisfactory, the two methods which have given the best results being excision of a portion of the tendo Achillis, and the division of the plantar fascia; of the latter he speaks more favorably.

TORTICOLLIS.

Auvard [23] reports a case of congenital torticollis, which, considering the lack of accurate knowledge of the pathological conditions at the time of birth in this class of cases, is a valuable contribution to the knowledge of this disease. This case is of more value as the child was still-born, and therefore the condition must have existed *in utero*, and also as a careful autopsy was made. The infant was the seventh, and there was no history of any value. The delivery was physiological, although the presentation was unusual. The head was drawn toward the left shoulder, and the face raised and turned to the right. The attempt to correct this deformity was arrested by a tense subcutaneous band. In other respects the child was well formed. The autopsy disclosed the following: About the posterior fontanelle there was overlapping of the cranial bones, the left parietal over the right, and the left parietal over, and the right under, the occipital. These were not reducible. After section of the insertion of the sterno-mastoid and trapezius, the deformity could be partly overcome. In cutting this a considerable resistance was encountered, as in fibrous tissue. Complete rectification did not take place until division of the interspinous and supraspinous ligaments. No abnormal condition of the vertebræ was found, and there was no compression of the cord. The brain was normal. As to the etiology, whether a result of a nervous influence or a primary muscular lesion, Auvard makes no attempt to prove. He has found no reported analogous case.

HARE-LIP AND CLEFT PALATE.

Clement Lucas [24] calls attention to a point which he thinks has never been described, viz., that a congenital absence of an upper lateral incisor may foretell the probability of cleft palate and hare-lip in a succeeding generation. Three illustrations are cited,—two in which the absence of the tooth repeated itself in the children, and one in which the absence of the upper incisor in the mother was associated with hare-lip and cleft palate in the infant. He considers the conditions analogous, showing a tendency to an arrest of development in the same direction, and concludes the following deduction to be irrefragable: "that the absence of a lateral upper incisor tooth resulting from an arrest of development is to be regarded as a malformation closely related to hare-lip and cleft palate, and capable of transmitting each or both of these deformities to a succeeding generation."

TREATMENT OF SPINAL CARIES.

Charles F. Stillman [25] describes a point in the construction of spinal support which he says is original with him and new in orthopædic surgery.

[23] Archiv de Tocologie, Aug., 1888, 494.
[24] Trans. Clin. Soc. Lond., 1888, xxi. 64.
[25] N. Y. Med. J., Oct. 27, 1888, 473.

It consists in making continual elastic pressure over the site of disease and deformity. In this are two strips of metal, thin enough to exert a spring action, surmounted by elliptical padded plates which are opposed to the site of disease; these uprights are secured to the pelvic bend, and their angle of adjustment so regulated by a ratchet that when the uprights of the brace are in place a varying amount of pressure may be exerted. The brace is held in position by the ordinary method of anterior support from the chest and abdomen.

When the disease is low in the dorsal or in the lumbar region, the uprights would be too short. They may be attached to the upper instead of the lower portions. In applying the apparatus the child is laid upon a table with the head and shoulders over the edge, and as they descend a partial extension of the spine occurs, and a tendency to obliterate the knuckle.

The tendency of the disease is to curve the body forward, and the force of this treatment is to counteract this tendency.

CHRONIC JOINT DISEASE AND CONSTITUTIONAL TREATMENT.

Gibney,[26] in view of the well-recognized opinion of the tubercular nature of the usual forms of spine, hip, and knee disease, considers the constitutional treatment one of importance, as in tubercular processes elsewhere, as in the lungs, although not to exclusion of local treatment. The constitutional treatment he has had opportunity to see well tried, and its value is not possible to estimate.

CONGENITAL DEFORMITY.

Raven[27] reports a rare case of congenital deformity of giant growth of the thumb and index finger of right hand. The increase in size involved both bone and soft parts. There was also a distortion to the ulnar side of the distal end of the index finger. The muscles of the ball of the thumb are large but soft, but the strength of the two members is diminished, and they are liable to be numb. The muscular development of the right arm is greater than left; otherwise there is no abnormality. No heredity. The patient, a young woman.

Clinical Department.

EXTERNAL URETHROTOMY FOR TRAUMATIC STRICTURE COMPLICATED WITH EXTENSIVE FALSE PASSAGE.

BY G. W. PERKINS, M.D.,

Division Surgeon, Union Pacific Railway.

A. B. C., American, twenty-four years old, single, and a freight brakeman, was caught, January 5, 1889, between a box-car and an engine, and severely squeezed antero-posteriorly across upper part of left thigh and left lower lumbar region. He was picked up suffering much from pain and shock, and soon had hæmorrhage from the meatus. Some hours afterward was catheterized with rigid metal instrument, which caused him great pain and brought only a little "pure blood." The doctor told him his "bladder had burst."

After this, till January 8th, a soft-rubber catheter was used two or three times in twenty-four hours, withdrawing from a half-pint to one pint of bloody urine each time. January 8th passed, himself, about a pint of nearly normal urine. Had moderate abdominal distention and much pain for first few days, but only slight rise of temperature and pulse.

Symptoms pointed to fracture of pelvis, but at first no positive evidence in the way of crepitus or increased mobility could be detected, either externally or through the rectum. After a few days an induration appeared in perineum, on left side, which remained for several weeks, but finally resolved without opening externally. Two or three weeks after injury, rectal examination showed thickening of left pubic ramus due to callus.

Patient improved slowly but constantly, and was walking about in six or eight weeks.

Symptoms of stricture developed very rapidly, and examination of the urethra about April 1st showed tight stricture six inches from meatus, through which I could get nothing larger than a No. 1 English gum-elastic catheter (about No. 6 French), and this evidently by accident or good luck only, as I could never afterward pass any instrument at all through into the bladder, though I tried certainly a dozen times, over a period of three weeks, with bougies of every kind. Patient passed a stream about size of No. 6 French, which was constantly getting smaller.

I advised a perineal operation, and patient consented. April 24th, etherized with Drs. Carnohan and Armstrong assisting, and put in lithotomy position; large sound passed down to the obstruction and held accurately in median plane of body and the canal opened near its tip by the usual median incision. A loop of silk was passed through each edge of the divided passage, and the anterior angle of the wound held open. Many small openings appeared on sides and at the end, and careful attempts were made, by probing, to pass soft and rigid fine instruments through these into the bladder, and by pressure on the bladder to force out urine to indicate the true opening; could neither get through, nor force out a drop of urine. The patient's bladder could hold but a few ounces, and he had not been able to retain any urine for some hours before operation, as ordered.

After nearly two hours spent in trying to find the passage, decided to postpone attempt to another day, when the parts were free from blood, rather than do a Cock's operation, which would have been very uncertain with bladder nearly empty, and moreover was not imperative to relieve retention from obstruction with extravasation. Drainage-tube, carbolic irrigation, and antiseptic dressing. Rallied well and very little discomfort; at 12 P.M. passed about a half-pint of clear urine, *exactly same as before operation, through meatus*, apparently not a drop through perineum. During 25th passed about a half-pint two or three times, wholly through meatus.

It was evident that, 1, the opening through which the urine came was *anterior* to the incision; 2, that the incision had either been made into a false passage which occupied the normal position of the urethra, or the urine was coming through a false passage which opened into the urethra anterior to the obstruction. Acting on this hint I, with the help of my colleagues, etherized the patient again April 26th, previously putting a ligature on the penis to retain the urine, introduced sound as before, bringing it out through perineal wound, holding its edges open with loops of silk, then cut with scissors, one-fourth inch at a time, along the sound as a guide, through all the tissues from the floor of the passage through the skin, and in direction from behind forwards. Not till I had gone distance of fully an inch and a half anterior to the cul-de-sac did an opening appear on the roof of the passage, into which I managed with great difficulty to pass, apparently through a sinuous track, a No. 5 French, conical, soft, black bougie. This was hugged so tightly that there was no room to pass along it a metallic guide, and I pushed a scalpel along its side, through a dense gristly substance, for one inch before urine flowed, dividing freely enough to pass a finger into the bladder. This passage was not in the middle plane of the body, but distinctly toward the left. It was evidently the true urethra displaced, either through inclusion in the callus of the fracture, which remains as a prominent knob on the pubic ramus, or from cicatricial contraction of extra-urethral tissues. A No. 12 English gum-elastic catheter was tied in through the meatus and kept in first two days; through this all the urine came; when removed, it all came through the perineum for twelve days, but was under perfect control; then gradually more and more came through meatus, and none came through perineum after the thirtieth day. For the first week bladder was irrigated every second day, through catheter, with saturated solution boracic acid, made to return through perineum. From the sixth day a large steel sound (26 to 30 French) was passed every second day. The patient made a perfect recovery, without chill or bad symptom of any kind; he now makes a stream as large as ever; passes, himself, a 26 French sound, and is as well as any one.

The chief interest of the case lies in the additional difficulty of an operation, — sufficiently difficult when uncomplicated — due to the presence of a large, long, false passage occupying the position of the normal urethra, while the true urethra was hardly more than a pin-hole on the wall of a canal large enough to admit 30 French instrument and one and a half inches anterior to the cul-de-sac.

Reports of Societies.

FORTIETH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION,

HELD AT NEWPORT, R. I., JUNE 25TH TO 29TH, 1889.[1]

SECTION IN MEDICINE, MATERIA MEDICA, AND HYGIENE — F. C. SHATTUCK, M.D., CHAIRMAN.

Third Day — Thursday, June 27, 1889.

The first paper of the afternoon was by Dr. V. C. Vaughan, Ann Arbor, Mich., on

THE ETIOLOGY OF TYPHOID FEVER.

In 1880 Prof. C. J. Eberth, of Zurich, in eighteen out of forty-eight cases of typhoid fever, found in sections of the spleen and mesenteric glands a bacillus which was distinguished from the ordinary putrefactive bacilli by the difficulty with which it took up the aniline stains. At the same time Eberth reported that in twenty-four similar examinations of those dead from other diseases he was unable to detect this bacillus, and from these facts thought himself entitled to claim that he had discovered the true germ of typhoid fever. Since that time various experiments had been made by many different observers. The attempts which had been made to induce the disease in the lower animals by inoculation with this germ were numerous and interesting. To sum up the evidence which we had upon this point we might say: (1) the Eberth germ was found invariably in the bodies of those dead from typhoid fever; (2) it had been isolated and grown in pure cultures; (3) all attempts to induce typhoid fever in the lower animals by inoculation with this germ had thus far been without success; (4) experiments showed not only that the germ failed to multiply in the lower animals, but that when introduced by inoculation it soon died.

Dr. Vaughan thought it was now time to add this rule to the four rules of Koch: before any micro-organism could be considered the true and sufficient cause of a given disease it must be shown that the chemical products of that germ were capable of producing the characteristic symptoms and lesions of that disease in an acute form. Did this germ produce any chemical substance which would markedly elevate the temperature, such as mydaleine, or any which induced local inflammatory and necrotic changes in the tissues, such as cadaverine or putrescine? We could not say that the Eberth germ had been demonstrated to be the true and sufficient cause of typhoid fever, judging from the failure of the attempts of Brieger in investigating the nature of typhoid poison. To sum up the results of experiments on this point: (1) the result obtained upon injections of the Eberth germ was found to be in direct proportion to the amount introduced; (2) that the Eberth germ did not multiply in the blood; (3)the same symptoms and lesions were obtained by the introduction of non-pathogenic organisms. To this the bacteriologist might reply that the lower animals did not have typhoid fever. If we could experiment with man the result would be different.

Dr. Vaughan then described his own experiments in attempting to discover a chemical poison excreted by the Eberth germ. He took the fæces of typhoid

patients, from which he obtained these germs. The germs were cultivated. His next step was to obtain a chemical poison which he succeeded in isolating. Crystals of this ptomaine were injected over the abdomen of an animal with resulting fever, severe purging, etc. This ptomaine was found to be most abundant when the culture was kept at about 104° F. Dr. Vaughan had not completed his series of experiments, and therefore had no definite statements to make respecting this alkaloid, to which he had not as yet given a name.

DISCUSSION.

DR. W. H. WELCH, Baltimore, agreed with the conclusions the reader had drawn from the experiments which investigators had made as to the pathogenic qualities of this typhoid bacillus in animals, but he protested against the setting up of a condition as essential for demonstrating the dependence of an infectious disease upon a micro-organism. He thought we were justified in considering that a germ was the cause of a disease when we found that germ invariably present in the disease in situations which would explain the symptoms of the disease, and when we failed to find that germ in any other circumstances than in that disease. If Dr. Vaughan's condition was to be accepted he did not know that there was a single disease which had been proven to be dependent upon a micro-organism. It was uncertain whether all micro-organisms which were pathogenic produced their effects by means of chemical substances which they formed. Doubtless that was true of some, but we were not justified in assuming that it was the sole method. He believed the evidence was conclusive that the typhoid bacillus was the cause of typhoid fever. It was a peculiar organism, which was found invariably, if we examined at the proper stage of the disease, in persons sick or dead from typhoid fever. It was found in the situations where we would expect the organism to be found, and had never been found in other situations, except in infected localities, as in drinking waters, etc. The isolation of the ptomaine in a crystalline form from the stools of typhoid fever patients was a very interesting addition to our knowledge, but it would be necessary to make investigations with other stools not infected with typhoid fever before concluding that the ptomaine had anything to do with the symptoms of typhoid fever.

DR. JAMES TYSON, of Philadelphia, said with regard to the fact that a chemical product must be discovered in the blood or tissues of the animal he would say nothing, but it seemed to him perfectly reasonable to expect that the same organism which had been found in the animal originally affected should also be found in the blood or tissues of the one in which the disease had been reproduced. That was the accepted original idea. It seemed to him that it would be very much more conclusive proof if we found the organism in the individual secondarily affected, that it was the cause of the disease, rather than if we simply found it in the individual primarily affected.

DR. V. C. VAUGHAN, in closing the discussion, said that Dr. Koch, in a conversation with him recently, had expressed the opinion that the Eberth germ had not been demonstrated to be the cause of typhoid fever. Koch had laid down four rules: before we could say that any germ was the cause of a given disease we must (*a*) find it in every case of that disease; (*b*) isolate it from all other material; (*c*) healthy animals of the same species inoculated with that germ must have that disease; (*d*) in the animals inoculated with this disease the germ must grow and reproduce itself. Where these rules had been complied with there could be no possibility of doubt about the germ being the cause of the disease. Dr. Welch asked us to give up every one of these rules save the first, and that we must say that a germ was the cause of a disease when we found it in every case of that disease. Germs depended on the conditions surrounding them. As long as the bacillus of tuberculosis was found in every case of consumption and in no other disease, and no consumption had been produced in healthy animals by it, he claimed he would have had just as much right to say that it was the result of the consumption as they would have to say it was the cause. The proof was not and could not be complete until that germ was isolated from all other material and healthy animals inoculated with it had consumption. Simply because the Eberth germ was found in every case of typhoid fever could not be a proof that it was the cause of typhoid fever. He did not mean to say that every germ produced its deleterious effects by means of its ptomaine, but did mean to say that this had been demonstrated for a number of diseases — for anthrax, tetanus, etc.

DR. JAMES C. WILSON, of Philadelphia, read a paper on

THE PROPHYLAXIS OF TUBERCULOSIS.

The tuberculous diseases, including pulmonary phthisis, we recognized to be specific infectious diseases produced by a tubercle. He wished to consider three questions: 1, was pulmonary consumption hereditary? 2, was it contagious? 3, was it preventable? The solution of these questions was a matter of the gravest consequence to mankind.

1. Was pulmonary consumption hereditary? We knew that bodily conformation, facial peculiarities, etc., were transmitted. The same was true of nervous organization. Diseases of the mind and diathetic diseases were transmitted. A syphilitic mother might bear in succession several children manifesting the effects of syphilis in varying intensity. Tuberculosis, in the large majority of cases, was a local process throughout its whole course, while syphilis and certain other infectious diseases had the element of infection in the blood. The tendency to localization of the process was shown in the lungs, where caseated patches were found post-mortem in patients dead from other diseases than tuberculosis.

The tuberculous diseases did not correspond in their pathology to the acute infectious diseases which were hereditary. That tuberculosis might be produced by infection of the semen or ova there was no evidence; that it might be caused by infection of the placental blood there was little evidence. We no longer spoke of the "tuberculous diathesis," because it did not exist any more than a typhoid diathesis existed. The puny offspring of

weak and diseased parents showed diminished resistance to disease and were especially prone to tuberculosis. That such children contracted infectious diseases did not incline us to call these diseases hereditary. The congenital predisposition to tuberculosis was much less general than to some of the eruptive diseases of childhood.

2. Was pulmonary consumption contagious? Tuberculosis was inoculable by all of the three recognized methods: (*a*) through foods and drink; (*b*) through the air; (*c*) by direct contact. There was no question at present that tuberculosis might be acquired by infected food, as the milk of tuberculous cows. Tuberculous sputum, alone or mixed with food, would give rise to tuberculosis in animals who ate this or to whom it had been administered. Inhalation of particles of dried sputum from tuberculous patients disseminated through the atmosphere might produce the disease. Experiments had shown that tubercle bacilli were present in the dust of rooms occupied by consumptives and absent in the dust of rooms occupied by people not suffering from this disease. The preponderance of pulmonary consumption over other forms of tuberculosis was to be explained by the greater exposure of the air passages to the bacilli. Another proof of the contagious nature of pulmonary consumption was its spread in the form of circumscribed epidemics, which were unnoticed because of the long duration of the disease. The development of the disease in married couples and in those nursing relatives suffering from it, also its great prevalence in cloisters, were in conformity to the view of contagion. The enormous spread of the disease among monkeys confined in zoological gardens and not in the wild state was also in conformity to this view. The tuberculous diseases, therefore, responded in every important particular to the tests by which we determined the contagiousness of other infectious diseases — it was transmitted by inoculation; by direct contact; by means of food and drink ingested, and, finally, by means of the inspired air.

3. Was pulmonary consumption preventable? If pulmonary consumption were hereditary in the ordinary sense any hope of prevention would be chimerical. What measures of prophylaxis could be exerted against the heredity and spread of a disease capable of showing itself at any time of life, or against a disease not only capable of transmission to the third and fourth generation but through a generation or two entirely free from it.

As the importance of heredity as an element in the production of pulmonary consumption diminished, that of contagion asserted itself more strongly. In contagion alone could we find a consistent theory of the spread of the disease and an intelligible explanation of the very facts to account for which the theory of heredity had been strained beyond reason.

The chief avenues of contagion were the digestive and respiratory tracts; and while in theory the spread of tuberculosis was preventable it remained to be seen how far it was in practice. The systematic care of milk, until consumed, to prevent the access of dust which might be infected, would be an important factor. The sputum of consumptives, which, when dried, became a fruitful source of the disease, should be collected in suitable vessels and kept in a moist condition until it was destroyed by fire or disposed of in such manner as not to become a source of danger. Consumptives should be cautioned not to spit upon floors or into handkerchiefs, for an individual who was well on the road to recovery might by self-inoculation, if he did not with the greatest care destroy his sputum, diminish greatly his own chances of recovery. It was important to communicate to the patient at an early date the true nature of his disease in order to secure his co-operation in the prevention of self-inoculation and in the prevention of the spread of the disease.

DISCUSSION.

Dr. C. G. Stockton, Buffalo, N. Y., believed in a tubercular diathesis to a certain extent. Some individuals exhibited a lack of resistance to the disease, and whether a person were resistant or non-resistant would determine whether he would have the disease. There was, in his opinion, something besides the mere contagiousness in this disease that determined its occurrence. There must be, first, contagion, and, second, soil.

Dr. S. E. Solly, Colorado Springs, found tuberculosis of the lungs in all sorts of people in Colorado. He thought there was overwhelming evidence of its contagious character. Those of the lymphatic type, perhaps, were more prone to take the disease.

Dr. H. J. Herrick, Cleveland, doubted the bacterial origin of tuberculosis, and thought it was not proved to be contagious.

Dr. S. S. Cohen, Philadelphia, thought it was still a question which was first in chronology, the organism or the disease. He believed there was a consumptive heredity, not a tuberculous heredity.

Dr. J. C. Wilson, Philadelphia, in closing the discussion, said the fact that there were certain problems in the question as yet not solved did not in his mind stand in the way of acceptance of the general doctrine. Pathologists were nearly unanimous in regard to the etiology of tuberculosis, and we must not be discouraged by clinicians who were unwilling to accept the doctrine. Those who opposed this theory did not offer anything in its place which was as reasonable and coherent as this theory.

Dr. M. R. Crain, Rutland, Vt., read a paper on

TOXIC AGENTS IN THE BLOOD AS A CAUSE OF DISEASES OF THE NERVOUS SYSTEM.

Dr. Crain called attention to multiple neuritis and the various toxic agents in the blood which might cause it, as arsenic, lead, alcohol, etc. Other blood-states productive of multiple neuritis were gout, rheumatism, septicæmia, and leprosy. Certain diseases of the nervous system, as locomotor ataxia, were cited in which we found lesions in various parts of the body, but these lesions were preceded, many of them, by toxic agents in the blood. Neurasthenia might be caused by overeating in case the person did but little and ate a great deal. Imperfectly digested food was introduced into the system, and hence the cause was a toxic agent in the blood. Many headaches were toxic. In every case of nervous disease it was necessary not only to locate the disease, and to say whether it was organic, but to examine and see whether any toxic agent in the blood was producing the trouble.

DR. W. L. SCHENCK, Kansas, presented

SOME THOUGHTS ON THE ETIOLOGY, PATHOLOGY, AND THERAPEUTICS OF PHTHISIS PULMONALIS.

Dr. Schenck considered at length the disease from the standpoints of etiology and pathology, and in conclusion announced it as a fundamental principle that without lowered vitality, general or local, there was no tuberculosis; hence the treatment of phthisis must be directed to the restoration and building up of degraded cells and tissues. The absence of fat tended to tuberculosis; its presence tended to prevent or cure tuberculosis. Alcohol had been recommended as *the* hydrocarbon in the treatment of phthisis, but the heat-producing power of alcohol compared with cod liver oil was as three to four in favor of the latter. In our treatment we must strive to improve digestion and assimilation, and we could not improve digestion without removing that which was useless. Alcohol "pickled" the tissues and tended to the retention of that which was useless.

DR. SOLOMON SOLIS-COHEN, Philadelphia, read a paper on

FOOD IN THE TREATMENT OF PULMONARY CONSUMPTION.

Though the paper is therapeutic, yet as therapeusis must be founded on sound pathology, it is necessary to state that the morbid physiology of the disease, and not its bacteriology, is considered the fundamental indication. In deference to prevailing views tuberculosis may for the present be granted to be the history of the growth, life, and activity of a bacillus. But for rational treatment we must revert to the views of Niemeyer, who said that the danger of phthisis is tuberculosis; or to those of Rush, who declared that tubercle and other anatomical lesions were "the effect not the cause of pulmonary consumption;" and recognize the disease we have to combat, not in epiphenomena of possible microbic origin, but in the consumption, the aberration of nutrition, which precedes the entrance of the microbe. Consumption is a disease of nutrition, whose exact mechanism is as yet unknown, though the results of prolonged observation justify us in considering heredity, unhygienic surroundings, and, in general, those influences called "depressing," as among its remote or proximate causes; the pulmonary form being further dependent upon errors in respiration, whether of the substances respired or of the performance of the act.

Thus we dismiss, as futile, microbicidal treatment; and recognize ptomaines of bacillary origin only as giving rise to intercurrent symptoms which may call for antidotal or symptomatic treatment. Fixing attention upon the malnutrition, which is not a mere "predisposition" to succumb to a bacillus, but the essence of the whole morbid process, we combat it by direct measures, hygienic and medicinal; the latter secondary, the former all-important. Chief among hygienic measures is food. Food consists not alone of meat and drink, but also of air. Full respiratory diet is necessary to the utilization of alimentary diet. As in diabetes, so in phthisis, there is imperfect metabolism of carbohydrates. Experience shows a nitrogenous dietary to be best. Debove has shown that consumptives can assimilate a quantity of food far in excess of the needs of the healthy organism. This excessive quantity should be supplied; though resort to the stomach-tube, as in Debove's experiments, can be reserved for special cases.

Meat, principally beef, with milk, fish, eggs, leguminous vegetables, and greens should form the bulk of the dietary, with the addition of fat in large quantities, in the form of cream, butter, oil dressing for salads, or, if necessary, cod liver oil or oleaginous inunctions. Alcohol is a food in consumption. It should be combined with malt, milk, glycerine, or cod liver oil. Not more than three, at most four, hours, except during sleep, should be allowed to elapse without taking food. Milk punch on going to bed, and a glass of wine or spirits with liquid peptonoids in case of waking during the night, are strongly urged. Hot water before meals, lavage if necessary, to prepare the alimentary tract for the digestion and absorption of increased food, and the free drinking of water to wash out waste products, are essential to success. Predigested foods may be employed with great benefit, especially peptonized milk and beef peptonoids. In case gavage is resorted to, they should be used almost exclusively. Gavage is best preceded by lavage with an alkaline solution and chloroform water. Proper alimentary diet being secured through over feeding, and the digestive tract and its adnexa being kept in good condition, proper respiratory diet must be supplied. Open-air life, exercise on horseback, or bicycle, voluntary respiratory gymnastics, may suffice when the patient is still strong enough. In the majority of cases there must be some artificial aid. The inhalation of compressed air, with or without expiration into rarefied air, is the best means. Apparatus should be simple and cheap, so that the patient can use it at home. The principles laid down by Waldenburg are the correct ones. Cohen's apparatus consists of a bellows and a small gasometer modelled upon Waldenburg's. Its advantages are cheapness, simplicity, and small size, fitting it for home use. After patients are sufficiently advanced towards recovery, the pneumatic resistance valves of the author, a still more convenient and very cheap pocket-apparatus (costing about $5) may be used. It may be used in the first instance with strong patients. It is also useful as a prophylactic measure with ill-developed children. It gives the effects of breathing against pressure, *i.e.*, into compressed air, or out of rarefied air.

The effects of pneumatic measures are to increase the volume of respired air, open up unused air-cells, facilitate expulsion of pathological products, increase gaseous exchange, facilitate absorption of oxygen by the hæmoglobin, while at the same time the volume of blood and the activity of circulation in the lungs is increased, bringing more corpuscles into contact with the increased volume of oxygen. Penetration of blood into the tissues, tissue respiration, and production of lymph are also increased. Thus local and general nutrition are powerfully stimulated, and an improved respiratory habit and increased respiratory and circulatory power are gained. The products of digestion are properly oxidized and utilized, immature tissue is destroyed and expelled. The promotion of sleep is one of the most marked effects.

The physician, by altering his patients' environ-

ment in the manner described, puts them into a condition where natural powers complete the cure, and bacilli need not be feared. Illustrative cases were cited, and the conclusion reached that the proper treatment of consumption is not microbicide, but nutrition.

Dr. J. A. Cutter, New York, read a paper on

TROPHOPATHY IN FATTY AND FIBROID DEGENERATIONS, WITH PRESENTATION OF CASES OF CURE.

SECTION OF OBSTETRICS AND GYNECOLOGY — W. H. WATHEN, M.D., CHAIRMAN.

Second Day — June 26.

Dr. Joseph Taber Johnson, of Washington, D. C., read a paper on

TETANUS FOLLOWING OVARIOTOMY.

So rare a complication of ovariotomy and the recent interest in the transmissibility of tetanus were his reasons for bringing this case before the section. The history of the case was, in brief, as follows: A solid growth, sarcoma of the ovary, the size of a child's head, was removed. The patient, who was aged sixty-one, recovered rapidly and without complication. On the morning of the thirteenth day she developed tetanus and died on the third day of the disease and fifteenth day after the operation. She exhibited numerous muscular spasms; mind clear, jaws locked. The convulsions were especially active in the neck and back, and during their presence the pulse was notably weaker. The patient died of what appeared to be heart-failure. No other patient in his hospital was affected with this disease, and it was the only case which had occurred in it during the eighteen months it has been in operation. It seemed to him that there was probably no outside influences. His horses were healthy and he does not drive them himself, so thought there could be no opportunity in this way. In all cases of inoculation the disease is contracted and the patient dies in a very few days, generally not more than three. His patient got along well till the thirteenth day. The author's case, the case of Homans, of Boston, and that of Richelot, of Paris, are the only cases of this complication he could find. The room in which the author had operated was thoroughly disinfected. The equine origin of this disease has been thoroughly discussed by Verneuil, of Paris, and much interest brought out by his investigations. Tait thinks tetanus will continue to be a complication of ovariotomy, and one which we can hardly explain or eliminate. The practical point of the paper was to draw attention to the infectious nature of this disease. He advised that care be taken as to infection, especially with horses.

Dr. A. Reeves Jackson, of Chicago, gave details of sixty-seven cases, more or less complete, in his paper on

INJURIES TO THE BLADDER DURING LAPAROTOMY.

Dr. A. Van Der Veer, of Albany, New York, read a paper on

CONCEALED PREGNANCY, ITS RELATION TO ABDOMINAL SURGERY.

Dr. Theophilus Parvin, of Philadelphia, read a paper on

CASUISTRY IN OBSTETRICS.

Zoroaster, long before Cicero, gave us the maxim which contained the teachings of Cicero, "In doubt as to whether an action is right or wrong, abstain." The order of Jesuits has given especial attention to this subject. Zoroaster's rule is excellent, but will not always do in obstetrics, because we cannot in all cases abstain; we must do something. Casuistry sometimes perverts, as in the case of the wife who excused her adultery by saying that she gave her body to her lover, but not her lips with which she had made her vows of fidelity. The treatment of ectopic pregnancy in its earlier stages is one of the pressing questions of the hour. The progress of science brings up new questions in casuistry in obstetrics. The ophthalmologist finds albuminuric retinitis in the pregnant woman, and tells her physician that the continuation of her pregnancy is at the peril of her vision, and possibly of her life. The speaker thought that woman, when pregnant, should be treated as well as other animals in a similar condition, and continence for months or years is possible and not injurious. Notwithstanding the many influences brought to bear on the physician to prevent conception he takes great responsibility who attempts to thwart nature's law — *lex, lex dura, sed lex.* The instances for imparting this information are exceedingly rare, and the nicest casuistry is necessary. This information, if given, will pass to those who have no cause for the prevention of conception, and it will become general, and a strong defence to female virtue is taken away. Craniotomy he considered one of the most painful, serious, and difficult questions in casuistry in obstetrics. He reported several cases where the operation had been performed and the child had to be killed after delivery, or partial delivery. Those who advise craniotomy on the living fœtus cannot decide on the measurements of the conjugate which demand it. The field of craniotomy is being steadily restricted, but that it will entirely disappear except for hydrocephalus, and according to Tait in two years, few are sanguine enough to believe. Amputation of the pregnant uterus is destined to occupy a more prominent position than it has yet done. It is yet to be decided whether hysterectomy or hysterotomy will save the larger number of patients.

Dr. Wm. H. Parrish, of Philadelphia, read a paper on

PELVIC ABSCESS IN THE FEMALE.

He divided this into three subdivisions, areolar, intra-tubal, and ovarian. Chronic pelvic cellulitis occurs only as a sequel to pelvic abscess. We usually have the history of gonorrhœa in the husband, dyspaneuria in the woman. He had never met with an areolar abscess dependent upon extension of gonorrhœal inflammation from the vagina or uterus directly through the walls of these organs into the pelvic areolar tissue. Chronic cellulitis, unless becoming such by complications, is a gynæcological myth, and has an existence only as an *ignis fatuus* in the brains of former members of the profession. Abdominal surgery has demonstrated in numerous instances that chronic cellulitis has no independent existence. That intra-tubal abscess occurs with very much greater frequency than areolar abscess

must appear to every one familiar with abdominal surgery. The successful treatment of pelvic abscess often demands an exercise of the most deliberate judgment and the highest operative skill. The doctor urged the necessity of operating early in every variety of curable pelvic abscess. The besetting sin of the family practitioner and the timid and doubting operator is to wait. In this delay the dangers become cumulative and the surgeon is asked to operate when the case has become hopeless. If the patient dies the practitioner is discouraged, and in his next case he waits longer still in the hope that pus may not form or that it may escape spontaneously. He thinks that in some of his cases suppuration has taken place, resolution followed, and so justifies his delay. Early surgical interference with the knife should be the rule in all varieties of pelvic cellulitis.

(To be continued.)

AMERICAN CLIMATOLOGICAL ASSOCIATION.

SIXTH ANNUAL MEETING, BOSTON.

Second Day — Tuesday, June 25, 1889.[1]

DR. VINCENT Y. BOWDITCH, President, in the chair.

DR. JOHN C. MUNROE, of Boston, read a

REPORT OF TWENTY-FOUR CASES OF ACUTE MILIARY TUBERCULOSIS.

The following analysis of twenty-four cases of acute miliary tuberculosis of the lungs has been made in order to furnish if possible some clues towards the detection of the disease that not infrequently bewilders the most careful practitioner. The cases have been taken from the records of the Boston City Hospital, and it is to the courtesy of the members of the staff of that institution that I owe the pleasure of presenting this brief consideration. For the use of some valuable private notes made on a number of the patients by Dr. Samuel Delano I feel greatly indebted also. All the cases were fatal, occurring within the last five years, and only those in which a post-mortem examination was made have been chosen. The number is too small to attempt to draw percentage conclusions, and some factors generally considered of importance have been passed over because of insufficient data. Fourteen patients were male, with an average age of thirty-eight years, that of the females, not including one child two and one-half years old, being only thirty-two years. The oldest, a man, was sixty-five years of age. Eight were between the ages of forty and sixty years. Over a half were born on or near our eastern shore; two were negroes. The majority were ill in February, March, and April. Their occupations were of various kinds, and apparently had no causative influence. Only three gave a phthisical family history. In twelve it was not phthisical, while in nine no history could be obtained. Three-fourths of all the patients had always been well up to the time of the present illness, and, although in thirteen cases the autopsy revealed a chronic tuberculosis in addition to the acute miliary process, yet of this group only a single patient had given a history of having suffered from phthisis. In fact, the remainder had always been looked upon as healthy. Even though there was a history of a cough for one or more months, in two-thirds of the cases it was noted as being slight with muco-purulent expectoration, and had excited no alarm except in one instance when several attacks of profuse hæmoptysis had occurred. A severe cough was recorded in two cases, but in each it had begun less than a month before admission to the hospital. Among the exciting causes might be mentioned the following: overwork and exposure in a damp cellar, several weeks of hard drinking with but little food, partial asphyxiation, measles, scarlatina, whooping cough with measles and vaccination, each in one case. About one-third of the cases gave a clear history of a marked chill ushering in the disease. A few more complained of feverishness and malaise, while headache was pronounced in a few others. Loss of flesh, strength, and appetite, wherever noted, came on rapidly and were very marked. Likewise night-sweats were always profuse.

The post-mortem examination in every case showed an acute miliary tuberculosis of the lungs, and so far as could be judged it was the important, or one of the important, pathological conditions. Thirteen showed in addition some degree of chronic tuberculous process going on, often with cavity formation.

In thirteen cases, divided almost equally between the acute and the acute chronic, there was a tuberculosis of the meninges, causing so marked symptoms during life that the diagnosis was strongly influenced.

DISCUSSION.

DR. A. L. LOOMIS: This is a subject which has interested me for a very long time. It has interested me mainly in diagnosis. I have in mind the case of a young man, twenty-six years of age, who came to New York from Chicago, from Dr. Jewett. I made the diagnosis of pericarditis. The signs were very distinct, without fever. There was in that case a temperature at no time over 100°. There was rapid emaciation. He died about two or three weeks after he came to New York, probably about two months after the first symptom. At the autopsy we found tuberculosis. There were miliary tubercles in the lungs. There were miliary tubercles found in every organ that was examined. There is one point in the diagnosis which seems to me to be a very important one, and that is the rapid emaciation which takes place in all of these cases that I have seen. It is not necessary for me to say here to you gentlemen who are so familiar with this class of cases, that the diagnosis in miliary tuberculosis is very often not made until the post-mortem. Not infrequently persons go through Bellevue Hospital, and are treated as cases of fever, when at the post-mortem are found traces of miliary tuberculosis.

DR. J. B. WALKER: In the report of a case of a mother nursing her first infant she developed a miliary tuberculosis which ran its course very irregularly. There was a rapid development of pulmonary symptoms during the early portion of the attack. During the cardiac development the pulmonary activities lessened. With the cessation of the cardiac symptoms there was marked infil-

[1] Continued from vol. CXX., p. 645.

tration. The curious point in the history was the development of the pericardial symptoms and their disappearance entirely after the gradual development of the disease towards death. At the time the cardiac symptoms disappeared her temperature returned to normal. It had been gradually going down, and towards the close it was the ordinary temperature of miliary tuberculosis.

DR. FREDERICK I. KNIGHT, of Boston, read a paper on

THE CLIMATIC TREATMENT OF BRONCHIAL ASTHMA.

If one seeks information on the selection of a suitable climate for an asthmatic patient he will soon realize that no successful attempt has been made to establish indications for preference of one climate over another for any given case of asthma, that changes of climate have been made usually in an experimental way, and have been often attended with aggravation of the symptoms.

The chief cause of this has been the mistake which has been made in trying to reduce all cases of asthma to one class, assuming that the ultimate cause and mode of development of this symptom was the same in all cases. This has led to the origin and promulgation of different theories which have been in turn advocated and abandoned.

The case of error of the medical man is greater than that of the blind man in Tolstoi's fable, because, while he may soon learn to interrogate all parts of the animal tendered to him for examination, he will also soon be made aware that there is a great variety of animals. The specialist is familiar with the kind of asthma occurring in his own field of practice. It will appear that in climatic as in medical treatment we must make an examination to ascertain the condition of the patient as far as it is possible to diagnosticate this, and not treat the name of the disease. Dr. Knight stated that in an attack of asthma there were three factors, a predisposing, a determining, and an exciting cause, and the removal or modification of any one factor might prevent the paroxysm. The first and last factors were pretty generally admitted, the second some authors put in the nose, some in the lung, &c., but it had better be stated as a morbid condition *somewhere* in the respiratory tract, initiation of which caused reflex phenomena in the bronchial tubes. There is no climate which is good for all cases of asthma, and we must carefully consider, when the patient presents himself for treatment, the nature of the factors in his case, which of them we intend to modify, and how far change of climate may be able to aid us in this.

DR. G. M. GARLAND, of Boston, read a paper on

THE PATHOLOGY OF HÆMOPTYSIS FROM CHRONIC PULMONARY DISEASE.

For the convenience of our discussion to-day we will assume that we are considering only cases of true pulmonary hæmorrhage, wherein all extraneous sources of blood-supply, such as aortic aneurism, cardiac rupture, etc., have been ruled out by the symptoms of the case. We can then roughly divide pulmonary hæmorrhages into two groups: (*a*) cases which present physical signs of pulmonary disease; (*b*) cases in which no physical signs of changes of lung structure can be found.

Our knowledge of the pathological causes of hæmorrhage in the first group has been thoroughly digested by Virchow, Thompson, and others. We know that hæmorrhages proper in this group come from deficiencies in the pulmonary system of vessels, while bronchial hæmorrhage, or leakage from the arterial supply of the bronchial tubes, is slight in quantity and simply streaks the accompanying secretions of these tubes. No inference can be drawn from the color of the blood as to its source, because the oxygenation of the pulmonary blood is so rapid that it is expectorated red. Traumatic injuries of the vessels, and aneurism and diapedesis are familiar causes of hæmorrhage in tuberculosis. According to Virchow, however, the greater number of hæmorrhages in phthisis comes from ulceration of the vessels. In the second group we find no clinical evidence of changes in the pulmonary parenchyma. We may indeed locate the presence of blood in the bronchial tubes, but this does not necessarily determine the seat of the leakage, because the blood is rapidly drawn off into byways and side issues quite remote from its point of escape. The presence of hæmophilia, scurvy, and habits of excessive drinking would lead one to consider alterations in the composition of the blood itself as a possible cause of hæmorrhage. Some evident point of departure for an embolus, the possibility of thrombosis, etc., are matters for consideration in diagnosis.

Pulmonary congestion is not of itself alone a prolific cause of hæmorrhage. In whooping cough and congestive bronchitis the amount of blood is rarely copious and is the result of violent coughing. One writer has observed that hæmorrhages are rare in acute maladies of the respiratory apparatus, and in pulmonary congestion which is not symptomatic of a cardiac affection are rarely accompanied by an expectoration of blood.

This brings us to the consideration of the heart as a factor of pulmonary hæmorrhage. Fernet says: "After tuberculosis, heart disease exerts the greatest influence in producing hæmoptysis, and mitral troubles stand pre-eminent in the causative list." Here also the element of exertion comes in, upon which Thompson lays so great stress. He says: "The influence of exertion in the etiology of blood-spitting has not received so much attention as it deserves from the amounts and frequency of the event, for cases occur in which hæmoptysis has followed some unusual exertion, in which no causative proof of pulmonary disease can be shown to exist." Prolonged exertion in walking and running leads to excessive hyperæmia of the lungs consequent upon the rapid emptying of the veins into the right side of the heart, and either the lungs give way under a condition of general congestion with extravasation of blood, or local troubles of a similar kind occur; or, on the other hand, the heart may become overstrained and give way in a condition of general dilatation.

Brown-Séquard has produced hæmorrhage in the lungs by lesion of the pons. Strauss speaks of the ecchymoses tabetiques upon the extremities, following severe pain. Faisans and Kellar describe subcutaneous hæmorrhages resulting from great moral commotions in neuropathic persons; vicarious menstrual hæmorrhages are a common experience, and

it is interesting in this connection to note that out of two hundred cases collected by Puech, hæmoptysis figures twenty-four times, *i.e.*, in 12½%. Great weight is laid by Virchow upon a certain condition of the arteries themselves, which he called *wallung* [orgasm]. And he evidently believed this wallung to be under the direct control of the nerves. Illustrations of this condition are observed in the pulsatio epigastrica of hypochondriacs; in the heat-flashes of women during the climacteric; in the pulsations of the head in cephalalgia; in the throbbing of the temporal artery with the toothache. Moreover, this sensation of wallung is also felt in the chest and sometimes followed by a hæmorrhage which removes the disagreeable sensation, according to the evidence of patients.

In conclusion, therefore, I would say that I believe that a more careful discrimination of our cases of pulmonary hæmorrhage would reveal some of neurotic origin.

(To be concluded.)

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

T. F. SHERMAN, M.D., SECRETARY.

REGULAR meeting, Monday, March 4th, at the Medical Library, 19 Boylston place. DR. H. W. WILLIAMS in the chair.

DR. F. W. PAGE read a paper on

A BUSSEY BRIDGE ACCIDENT CASE: A REVIEW AND A CRITICISM.[1]

DR. NICHOLS said the society was under obligation to Dr. Page for the very careful manner with which the paper was drawn up. It is often very difficult for the expert who may be summoned for a corporation or for the defence to know exactly what course to pursue. If he states at the outset that he believes the plaintiff to be a malingerer he is apt to prejudice the rest of the testimony which he may have to present; the physician too often shows a lack of moral courage in not stating to the jury exactly what he believes. A different course is pursued in Germany: there, if the expert believes the plaintiff to be an impostor, he says so in so many words; here, the expert is much more cautious, and says, "the plaintiff in all probability is not so badly injured as he believes himself to be." If a different course was pursued here, Dr. Nichols believed that many of the excessive verdicts would be avoided. With regard to the symptom of local anæsthesia, he thought too much stress was apt to be placed on the effect of sticking a pin into the flesh, as many persons can stand the thrust of a pin without showing any signs of being hurt; he is accustomed to use a needle, as in electrolysis, adding a few cells at a time till pain is felt.

DR. PRINCE said that the paper of Dr. Page was a model of what such papers should be; many similar papers are so lacking in detail and in the methods employed in making the examinations that the report is of little value except to record the opinions of the writer.

Anæsthesia is a very easy thing to simulate and a very difficult thing to detect; the method recommended by Dr. Nichols in the use of electrolysis to detect anæsthesia, he should think would be of great value, and he should use it hereafter; if a sufficient number of cells were used it would be impossible to simulate anæsthesia.

DR. J. ORNE GREEN read a paper on

CLINICAL OBSERVATIONS IN AURAL PRACTICE.[2]

[1] Publication deferred.

Recent Literature.

The Bacteria in Asiatic Cholera. By E. KLEIN, M.D., F.R.S., Lecturer on General Anatomy and Physiology in the Medical School of St. Bartholomew's Hospital, Professor of Bacteriology at the College of State Medicine, London. London: Macmillan & Co. 1889.

This volume of one hundred and eighty pages is reprinted from the pages of the *Practitioner*, where the articles originally appeared between October, 1886, and May, 1887. The more recent contributions of Koch to the knowledge of the comma bacilli have been added to the text. The author holds to the opinion, in which he coincides with Pettenkofer, the English cholera commissioner, and others, that this comma bacillus is not the proved cause of cholera; though he agrees with Koch that the bacilli are constantly present in the cholera intestine and discharges during the early stages of the disease. The book is well illustrated.

Transactions of the Gynæcological Society of Boston. New Series, Vol. I. Cupples & Hurd. 1889.

The present volume of Transactions is the first permanent record of the work of the Gynæcological Society of Boston since 1872. That the society has not been idle in the meantime these admirable papers clearly show, and the recent date of many of them is an indication of renewed activity.

The twenty-eight communications which compose this volume naturally vary in interest and value. Of especial merit are The Ethics of Abortion, by J. E. Kelly; The Dress of Women, by Helen L. Betts; The Obstetric Forceps, by S. N. Nelson; The Perineum: its Anatomy, Physiology, and Methods of Restoration after Injury, by H. O. Marcy; and The Diagnosis and Treatment of Cancer of the Breast, by J. Collins Warren. Many of the others are eminently practical and suggestive, and taken as a whole they form a valuable collection for study and reference. They have been issued in an exceedingly neat and attractive form by the publishers.

Handbook of Physiology. By W. MORRANT BAKER, F.R.C.S., and V. D. HARRIS, M.D. Lond. Twelfth edition, rearranged, revised, and rewritten, and with five hundred illustrations. New York: William Wood & Co. 1889. pp. xi, 784.

This new edition of Kirke's familiar handbook will probably and properly find favor with those students who seek a book of moderate size and adapted to a similar capacity of the reader. The book has been improved by a considerable rearrangement of the material and by the addition of several useful plates, diagrams, and tables. The revision is in some particulars (*e.g.*, glycogen, urea production, peptones) not quite on a level with the best and more recent investigations.

THE BOSTON
Medical and Surgical Journal.
THURSDAY, JULY 18, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

All communications for the Editor, and all books for review, should be addressed to the Editor of The Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money order, draft, or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

TWENTY-FIFTH ANNUAL REPORT OF THE BOSTON CITY HOSPITAL.

THIS report presents the usual statistics setting forth the work done for the "sick poor" of the city of Boston during the year 1888. From these we learn that 6227 patients were treated in the hospital during the year, of whom 772 died, giving a mortality rate of 12.3 per cent.; but 314 died within 48 hours after admission, and if these are deducted the mortality rate would be 7.3 per cent. There were also 176 deaths from diphtheria, and as these were almost hopeless cases they ought also to be deducted in estimating the rate of mortality. The mortality at an institution where no one is too sick or too wretched for admission, and to which many cases are sent which have proved too serious for other hospitals and for outside medical relief, is necessarily high, and last year at this hospital, owing to an unusual prevalence of diphtheria and other causes, has been higher than before.

Of those admitted 3253 were medical, 2543 surgical, and 79 ophthalmic patients; 3665 were males, and 2210 females; 1721 were of Irish nativity, 1354 were born in Boston, 640 in the British Provinces, 362 in Massachusetts towns, 297 in England, 264 in Maine, 146 in Germany, and the rest in varying numbers in other parts of the United States, and in all parts of the world. Italy furnished 96, Scotland 90, Sweden 82, Russia 64, etc., etc. The largest number at any time in the hospital was 441, the smallest 320; the daily average number of patients was 378. The average time of remaining in the hospital was 22.21 days. The average net cost per patient per week for the year 1888 was $7.91 against $7.41 for the year 1887, $7.52 for the year 1886, and $8.39 for the year 1885.

The total expenditure during the year was $203,206, of which $17,045 was for additions, alterations, and renovations. The income from paying patients was $27,946.

Of diphtheria, 382 cases were treated during the year, with a mortality of 48 per cent. A large number of these were very young children suffering with septic symptoms or in the last stages of diphtheritic laryngitis, of Italian, Portuguese, or other foreign parentage, and were hopeless from the time of admission; there were 61 tracheotomies, of which 54 ended fatally, 107 intubations, with 78 deaths, and 17 cases in which intubation and tracheotomy were both performed, all of whom died.

In the out-patient department 13,383 patients were treated during the year, of which 5910 were surgical, 2991 medical, 1600 ophthalmic patients, and the rest came to the various special clinics for the skin, the ear, the throat, the nervous system, and for diseases of women.

The report justly condemns, as unquestionably bad, the policy under which contagious diseases, such as scarlet fever, measles, diphtheria, and typhus fever, are received in buildings in somewhat close relations with other wards of a general hospital. A special hospital for such cases, under charge of the Board of Health, with requisite authority for control, would relieve the General Hospital of a class of cases it ought not to receive. Such a hospital will involve increased expenditure, and will have to await a more enlightened public conscience and a less depleted city treasury.

An electric light plant is suggested as an improvement "not only demanded by the times, but especially needed in wards occupied by large numbers of sick people. The superintendent states that: "As an ordinary gas-burner consumes as much oxygen as five adults, so in some of the wards the oxygen consumed by the gas-lights is equivalent to twice the amount used by the patients. This means that three times as much oxygen is consumed when the wards are lighted as during the day when no gas is burning. Recent analyses of the air in the wards prove that the amount of carbonic acid gas in the wards during the day-time is constantly low (3.6 per cent.), and with little variation. This percentage rises rapidly after dark, and has been found as high as 11.4 per cent., which is near the danger-line, and practically means crowd-poisoning."

The training school for nurses in its eleventh year graduated twenty-one pupils; as proof of graduation a badge has been established which graduates may be required to exhibit.

This hospital is undoubtedly among the very best municipal hospitals in the world, but the demands upon its resources are constantly growing and its work is often much hampered by insufficient appropriations; this being the case, it seems idle to hope for the establishment of a special hospital

or hospitals for contagious diseases, at least in the immediate future.

TREATMENT OF NEPHRITIC COLIC AND GOUT BY THE GARDEN BEAN (*Vicia faba*).

A WRITER in the *Bulletin Général de Thérapeutique* (March 15th, 1889) extols the usage in nephritic colic, renal lithiasis, and gout of an infusion of the flowers of the garden bean. He speaks of this having been a standard remedy from time immemorial on the coasts of Calabria and in the south of Sicily, where the waters are hard, and where renal lithiasis is very common; the natives are in the habit of resorting to bean-flower tea when afflicted with calculous affections. The writer in the therapeutic journal alludes to his own experience in the use of this remedy. For more than thirty years he had been subject to attacks of renal colic; a strong decoction of bean flowers (which he took pains always to gather in their season) always rendered him signal service. He also bears testimony to the benefits which persons afflicted with gout have derived from this infusion of bean flowers. An infusion is made by steeping a drachm and a half of the flowers in a teacupful of water. This entire quantity is drank during the day, and it is recommended to continue this treatment for several months. A vicar of the suburbs of Dijon, an Italian count, is quoted as having said: "If this remedy does not cure gout, it certainly enables one to live with the gout without suffering." A common way of using this remedy in Calabria is to steep three drachms of the flowers of the bean in a quart of water and reduce this quantity one-half by boiling. To be freely drank by the patient.

The above indicates a use of the garden bean which will certainly be new to most persons in this country.

MEDICAL NOTES.

— The recent legislature of Texas voted $50,000 for the establishment at Galveston of a medical branch of the State university.

— Dr. Kiernan says he will not resign his position of superintendent of the Insane Asylum, as requested by the Cook County Commissioners, and that if the board wishes to get rid of him it will have to pass a resolution discharging him.

— The trustees of Roper Hospital, Charleston, S. C., have decided to repair the old building on Queen street, which was so badly damaged by the earthquake of 1886. The contract has been awarded, but none of the papers have as yet been signed. Just what use the building will be devoted to has not yet been determined.

— Dr. Henry M. Hurd, now superintendent of the State Hospital for the Insane at Pontiac, Mich., in the neighborhood of Detroit, has accepted the office of superintendent of the new Johns Hopkins Hospital in Baltimore. He is a man of about forty-five years of age, whose life has been devoted to hospital service, and he has acquired distinction as an administrator and also as a writer. He graduated in arts and in medicine at the University of Michigan, and has twice been called by his alma mater to a professorship of medicine.

— The addition which is being made to the Maine General Hospital will make the building about double its present size. The present structure consists of large square building with a long wing. The new building will consist, first, of a building 40x40, and of the same height as the present one. These will be connected by a corridor 16 feet wide. Added to this will be a building 38 feet long and 33 feet wide, which will be used for the wards. Across the end of this, at right angles, will be the third part, which will contain the apartments of the house doctors, and will be 60x25. The total length of the new structure will be 140 feet, with a width of 33 feet.

— The Kentucky Court of Appeals has made an interesting contribution to the literature of excise law.

A local option statute of Kentucky prohibits the sale of liquor as a beverage, but allows druggists to sell it for medicinal purposes on a prescription written and signed by a "regularly practising physician." The Act then provides that —

"No physician shall make or sign any such prescription except the person for whom it is prescribed is actually sick and such liquor is absolutely required as a medicine."

The Kentucky Court of Appeals has rendered a decision holding that if this provision is to be construed literally to mean that the physician is liable to punishment if the liquor was not "absolutely required" by the patient, then the statute is unconstitutional. "To make him a warrantor," the opinion says, "that the particular drug he prescribes is absolutely necessary for the disease, and for a breach, the result of an honest mistake, to mulct him in a fine, would drive him from the field."

But it is not necessary, the court goes on to say, to give the Act so rigid a construction. All it means is that if the person is actually sick, and the physician, after making a reasonably full and fair investigation of the disease, believes in good faith that his patient needs the whiskey as a medicinal remedy, and prescribes it, he is not guilty of violating said section.

— Judge Prendergast, of Illinois, has rendered a full and very damaging decision as to the condition of the Cook County Insane Asylum. The case came up on the petition of Dora Willard, through her sister, for release from the asylum, which is granted on the ground that the asylum is not a fit place for her detention. After enumerating the abuses found to exist the judge says: —

"The foregoing is but an incomplete reference to the facts adduced in this investigation. To a great extent workmen and attendants have been appointed on political grounds, and the constant care of these persons is to retain their places and cultivate the friendship of the powers that be instead of studying to increase their efficiency and skill as attendants upon the insane.

"Carried on under the guise of benevolence, this institution is in fact a monument of inhuman neglect. The county board claims to be utterly unable, under existing legislation and in view of the financial condition of the county, to do anything substantial toward remedying this condition of things. The fact is that there is no insane hospital or asylum in Cook County. There is a place of imprisonment that we call an asylum, and to this place we have committed about one thousand unfortunate insane, as to a tomb for the living, little less dreadful than a tomb for the dead in its worst state."

— From an entertaining book called "The Story of Patsy," by Kate Douglass Wiggin, which illustrates the attempt to apply modern educational methods to the very poor children of our large cities, we copy the following letter from "a mental heeler" in excuse for the repeated tardiness of her son. It is too life-like to have been invented: —

Miss Kate: Dear Madam: You complain of Lafayette's never getting to school till 11 o'clock. It is not my affare, as Hildegarde has *full charge* of him and I *never* interfear, but I would sujjest that if you *beleeve* in him he will do better. Your unbeleef sapps his *will powers*. You have only reprooved him for being late. Why not incurrage him say by *paying* him 5 cents a morning for a wile to get among his little maits on the stroak of nine? "Declare for good and good will work for you," is one of our sayings. I have not time to treet Lafayette myself, my business being so engrossing, but if you would take a few minutes each night and *deny Fear along the 5 avanues* you could heel him. Say *there is no Time in the infinit* over and over before you go to sleep. This will lift fear off of Lafayette, fear of being late and he will get there in time. Yours, for good,

Mrs. Powers, Mental Heeler.

Miscellany.

ENDEMIC CANCER.

The Paris correspondent of the *Therapeutic Gazette* gives some interesting facts collected by Dr Arnaudet, of Cormeilles, in Normandy, bearing upon the question of the contagiousness of cancer, which tend to prove that the disease may, under some circumstances, be communicated from one patient to another. In the little village of Cormeilles, with a population of four hundred in 1881, no less than eleven deaths from cancer, out of a total of seventy-four, occurred during the eight years elapsing from 1880 to 1887. So large a proportion for a comparatively infrequent affection is almost equivalent to an epidemic, and was all the more remarkable that the cancers were located in the stomach, neck, or mesentery, and carried off ten male patients against one female. As compared with Paris, the whole mortality from this cause was not only considerably larger, but the proportion of sexes entirely different, the usual rate in Paris being fifteen female to nine male cancer patients. The mortality at Cormeilles may be set down at ten times that in the capital, which is considered to present a fair average. The unusual proportion of male deaths in the village is, according to Dr. Arnaudet, owing to the fact that while in the city the uterus is often the seat of the disease, at Cormeilles the cancer almost invariably located in the stomach, and never once in the womb. Other Norman towns, as inquiry from brother physicians proved, showed a similar state of affairs. On grouping together the cases, and comparing the circumstances, too long to be here related, Dr. Arnaudet has come to the conclusion that there is no doubt of the transmission of cancer from one patient to another, and thinks the contagion has, in the present instance, had for a vehicle the water from village ponds used for making cider, the popular drink in Normandy. Cider-drinkers have been shown by medical statistics to be remarkably free from stone and urinary calculi. The immunity would be dearly purchased if cancer in the stomach is to be the price, were it not that Norman peasants can easily escape the dilemma by mixing their cider with none but pure water.

Correspondence.

PARIS LETTER.

FROM OUR SPECIAL CORRESPONDENT.

MICROBIOLOGY IN THE PROPHYLAXIS OF INFECTIOUS MALADIES; SUPPURATIVE COXALGIA; ACTION OF COCA ON THE VOCAL CORDS.

Paris, 21st June, 1889.

In a work on microbiology in the prophylaxy of infectious maladies, Dr. Fernand Roux makes some critical remarks which may be considered worth noticing here. Microbiology, he says, is a new science which has revolutionized medicine and has

proclaimed the pretension of establishing the prophylaxy of infectious maladies on a scientific and precise basis. This pretension has found few contradictors, and it has been admitted without restriction by certain confrères who preside over the destinies of official hygiene. It has often been asked what great progress microbiology has made since its introduction into medicine as regards the prophylaxy of contagious maladies. Cholera, which threatens us continually and which has been the subject of extreme interest, has been selected for investigation. It will be remembered the sensation that was caused in Europe by the discovery of the comma microbe which Koch affirmed to be the pathogenic agent of cholera. Admitting, for a moment, the correctness of this opinion, which is known to be contradicted by the majority of English physicians, the author asks what prophylactic results the discovery of Koch has produced? He cites the researches of MM. Gamaleïa and Yvert, which he says are not at all conclusive. For instance, pigeons that had been experimented on, and which died without presenting any symptoms of cholera after having been inoculated with a culture of the comma microbe, are registered as having been affected with cholera. M. Gamaleïa pretends that a person may be given a certain immunity against cholera by previously inoculating him with the attenuated disease. Such a theory may hold good with certain infectious maladies which, like the yellow fever, generally affect the same person but once, but this is not the case with cholera. A first attack of this affection does not afford the least immunity against a second attack. It may be predicted that the attempts that may be made in the direction followed by M. Gamaleïa shall be condemned to non-success. As regards M. Yvert, the prophylaxis which he says that he has discovered is extremely simple. The bichloride of mercury kills the microbe of Koch. Therefore, by administering it to patients affected with cholera they are cured, and by giving it to persons exposed to cholerigenic miasmata they would be protected against the disease. This theory would seem rational enough, but it is not confirmed by practice. M. Yvert says that he had obtained very good results with the bichloride during his practice at Tonquin. This method had been tried for a long time in India by the English physicians, and it did not prove more efficacious than the other remedies. As to the prophylactic value of the bichloride, if it be correct, observes Dr. Roux, the syphilitic patients submitted to the classical treatment should be protected against cholera. It has, however, been proved that the mercurial treatment is not only not prophylactic, but, as it troubles the digestive functions, it would constitute more a favorable cause to the development of the malady. In comparing, on the contrary, the results obtained by hygiene in the prophylaxy of cholera, we find that they are absolutely marvellous, and they have been obtained by the English physicians in India by observation alone and the study of epidemics, without a single theory being advanced. From 1826 to 1844 there died, on an average, annually from cholera 35 per 1000 inhabitants. At the present time the mortality has fallen to 2 per 1000. This almost incredible result has been obtained by simply substituting filtered water for that which was employed without taking into consideration from whence it came. Everywhere where this substitution was effected the cholera has diminished in such proportions that it may be admitted that the Europeans in India are protected against the disease if they do not commit any imprudence. At Calcutta, before 1870, the average mortality from cholera was 10.1 per 1000. Since this period, from which dates the establishment of pipes of filtered water, the mortality is 3 per 1000, having diminished by more than two-thirds. This result can only be attributed to the distribution of filtered water to the inhabitants. That which absolutely proves this fact is that in December, 1877, one of the principal reservoirs was seriously damaged, in consequence of which the distribution of filtered water was suspended for some time. The cholera, which before the accident was at its normal rate, assumed an ascending progression, and diminished as soon as filtered water was redistributed for consumption. It is true that enthusiastic microbiologists may say that precisely it is the microbe discovered by Koch, and which exists in the water, which propagates the cholera, and that consequently the prophylaxy of the malady proceeds from this fact. It may, however, be observed that a great number of English physicians, and those not among the least eminent, refuse to accept the ideas of Koch. The filtered water distributed at Calcutta does not pass on filters capable of retaining a microbe as small as the comma bacillus. Even should the theory of Koch be correct, it is not the less certain that the English physicians, ten years at least before the works of the German professor, had discovered the veritable prophylaxy of cholera, without having recourse to any theory whatever, and only by patient and repeated observations of choleraic epidemics. It may therefore be said that the prophylaxy of cholera was known, and put in practice, for some time in all parts of India by the English. After other critical remarks as to the futility of microbiology so far as regards the prophylaxy of cholera, the author declares that he has no intention of depreciating microbiology, which has rendered, in surgery, such considerable service that it has transformed this science. But when microbiology is introduced into medicine, and particularly into hygiene, it cannot have the same pretensions.

For some years past there have been many microbian theories developed, but all impartial medical men will acknowledge that as regards the prophylaxy of infectious maladies nothing new has been done. At least that which is given as such had been known and put into practice for a long time past. "It is certainly difficult to study and to follow step by step the progress of epidemics, to collect with care all the circumstances which favored them, or diminished their intensity. It is a fastidious work and gives but little credit to those who devote their time to it. It is otherwise convenient to find a microbe which gives glory and often profit to its discoverer. But, as regards serious results, the first method is the only one which, for the greater part of the maladies, and particularly for cholera, has useful effects. It is this which the English physicians have followed with success in India. We have only to read their works, and

shall not find in them a single word of theory, but the most interesting practical results. Should anybody have any doubt about the matter, he has only to recall to mind the considerable diminution of the mortality from cholera in India." The above remarks by Dr. Roux are worthy of consideration, as he had practised for several years in the French possessions in India.

Prof. Ollier, of Lyons, recently read a note at the Academy of Medicine on the distant results of the resection of the hip-joint in cases of suppurated coxalgia, regarded particularly in view of its definitive results. Since 1860 M. Ollier had practised this operation about fifty times, but he gives an account of the most ancient ones, which amount to fourteen, as it is only after a very long time that one can appreciate the results. These results show, without any doubt, that after the resection of the hip-joint, when it concerns a suppurated coxalgia, anchylosis is the termination which gives to the limb the *summum* of function for an active life. This anchylosis was generally obtained each time that the resection was properly performed under the periosteum, and that all the fibrous tissues of the old articulation had been carefully preserved. When the femur is anchylosed in a favorable position, with a slight flexion, the operated subjects may give themselves up to the hardest work and become indefatigable walkers. Once the anchylosis is established, there is nothing to be feared, in the way of secondary displacements, or of tuberculous or inflammatory foci. To sum up, one must, in the great majority of cases of suppurated coxalgia, seek to obtain anchylosis. However, one might preserve articular mobility when an early resection is practised, that is to say, as soon as an abscess around the articulation is suspected or established, because then the extent of the lesions of the soft parts being reduced to a minimum, one can hope for a very complete reparation of the articulation. Nevertheless M. Ollier does not recommend this procedure in all cases, as in many instances of suppurated coxalgias of childhood one can obtain cures by operations more simple than resection, such as the antiseptic opening of foci, injections of iodoform, drainage, etc.

A very interesting communication was recently made to the Société de Médecine Pratique by Dr. Sandras, who showed the falsity of the opinion that coca wine is the tightener *par excellence* of the vocal cords. The contrary was demonstrated by Dr. Sandras at the meeting of the society. After having sipped a tablespoonful of coca wine his voice became profoundly altered in intensity and tone. He therefore concludes that the coca wine paralyzes the vocal cords instead of strengthening them.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 6, 1889, TO JULY 12, 1889.

By direction of the Acting Secretary of War, the retirement from active service this date, by operation of law, of Colonel THOMAS A. MCPARLIN, Surgeon, under the provisions of the Act of Congress approved June 30, 1882, is announced. Colonel McParlin will repair to his home. Par. 2, S. O. 157, A. G. O., July 10, 1889.

SMITH, ANDREW K., Colonel, Surgeon U. S. Army, promoted Surgeon with rank of Colonel, to rank from July 10, 1889, vice McParlin, retired.

TOWN, FRANCIS L., Lieutenant-Colonel, Surgeon U. S. Army, promoted Surgeon, with rank of Lieutenant-Colonel, to rank from July 10, 1889, vice A. K. Smith, promoted.

By par. 1, S. O. 154, Hdqrs. Divn. of the Atlantic, July 9, 1889, Capt. H. O. PERLEY, Assistant Surgeon U. S. Army, is ordered to accompany troops from Fort Wayne, Mich., to Gognac Lake, Mich., to encamp there with the Michigan State troops from August 8th to 13th, 1889.

By par. 2, S. O. 154, Hdqrs. Divn of the Atlantic, July 9, 1889, Capt. H. O. PERLEY, Assistant Surgeon U. S. Army, is granted fourteen days leave of absence, to commence about July 14, 1889.

Leave of absence for one month is granted Capt. W. C. GORGAS, Assistant Surgeon, to take effect on the arrival of a medical officer to relieve him. Par. 2, S. O. 84, Hdqrs. Dept of the Missouri, July 3 1889.

By the direction of the Secretary of War, Captain ANDREW V. CHERBONNIER, Medical Storekeeper, will in addition to his present duties take charge of the office and perform the duties of Acting Assistant Medical Purveyor in St. Louis, Missouri, during the absence of Capt. GEORGE T. BEALL, Medical Storekeeper. Par. 2, S. O. 151, A. G. O., July 2, 1889.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING JULY 13, 1889.

WHITE, S. STUART, Assistant Surgeon, ordered to the Naval Hospital, Brooklyn, N. Y.

WHITE, C. H., Medical Inspector, detached from the "Trenton" and wait orders.

NORFLEET, ERNEST, Passed Assistant Surgeon, detached from the "Trenton" and to the "Monocacy."

AMES, H. E., Passed Assistant Surgeon, detached from the "Monocacy;" proceed home and wait orders.

HARRISON, G. E. H., Surgeon, detached from the "Constellation" and to the Naval Academy.

LOWNDES, C. H. T., Assistant Surgeon, detached from the "Constellation" and to the Naval Academy.

HARVEY, H. P., Surgeon, detached from the "Vandalia," July 7; proceed home and wait orders.

WHITE, S. STUART, Assistant Surgeon, detached from the "Trenton," July 7, 1889.

SOCIETY NOTICE.

NEW YORK STATE MEDICAL ASSOCIATION, FIFTH DISTRICT BRANCH. — The seventh special meeting of the Fifth District Branch of the New York State Medical Association will be held in Port Jervis, Orange Co., N. Y., on Tuesday, August 27, 1889. For those who are willing to spare the time after the meeting, a beautiful and interesting carriage drive of seven miles along the Delaware River to Milford, Penn., is promised. All are urged to make an effort to attend this meeting, as the committee of arrangements is making every preparation to insure an interesting meeting — both scientifically and socially

W. T. LUSK, M.D., President.

E. H SQUIBB, M.D., Secretary,
P. O. Box 94, Brooklyn.

THE CARTWRIGHT PRIZE.

The Committee of the College of Physicians and Surgeons of New York to award the Cartwright Prize send the following announcement: —

At the recent commencement of the College of Physicians and Surgeons of New York it was announced that the Cartwright Prize had been awarded to an essay written conjointly by Dr. Robert A. Hare and Dr. Edward Martin, of Philadelphia. But the successful competitors voluntarily surrendered the prize because their essay had just been awarded a prize elsewhere. It appears that the essay had been put into competition for both prizes, with the expectation that the decision of one prize would be made early enough to permit them to withdraw from the second competition in case they were successful in the first. But owing to delay in the decision of the prize which should have been announced first, and to the absence of the authors from home when the announcement was finally made, there was no opportunity for the intended withdrawal before the award of the Cartwright prize was published.

The award of the Cartwright prize has consequently been reconsidered, and the prize has been granted to Dr. Ira Van Gieson, Assistant Instructor in Normal Histology in the College of Physicians and Surgeons of New York, for his essay entitled "Studies in Neural Pathology, embracing (1) A Report of a Case of Syringo-Myelia; and (2) A Contribution to the Pathology of the Laryngeal and other Crises in Tabes Dorsalis."

DEATH.

Died in Northampton, July 11, 1889, AUSTIN WHITE THOMPSON, M.D., M.M.S.S., aged fifty-four years.

A CONSIDERATION OF THE USE OF GASES IN PENETRATING WOUNDS OF THE ABDOMEN.

BY HERBERT L. BURRELL, M.D.

Before the American Medical Association, at its meeting in May, 1888, Dr. Senn demonstrated what he termed an infallible test in the diagnosis of visceral injury of the gastro-intestinal canal in penetrating wounds of the abdomen by the rectal insufflation of hydrogen gas.

The importance of being able to detect an injury to the gastro-intestinal canal without performing a laparotomy was evident to the minds of most practitioners, and the thought which Dr. Senn had carried into effect of detecting a perforation in the gastro-intestinal canal by hydrogen gas at once placed it among the brilliant innovations. His method, in short, was as follows: —

Hydrogen gas, being insufflated into the rectum, would pass up the intestinal canal, through the perforation in the intestine, into the peritoneal cavity, and out through the wound in the abdominal parietes.

When it appeared at the abdominal wound it was there lit, a slight explosion occurred, and a bluish flame resulted.

After careful experimentation on a large number of dogs, Dr. Senn had concluded: [2] —

"That the entire alimentary canal was permeable to rectal inflation of air or gas under a pressure of from one-fourth of a pound to two pounds. That inflation of the entire alimentary canal from above downwards, through a stomach-tube, seldom succeeds, and should therefore only be resorted to in demonstrating the presence of a wound in the stomach or its immediate vicinity. That the safest and most effective rectal insufflator is a rubber balloon large enough to hold 16 litres of air or gas.

The resisting power of the intestinal wall is nearly the same throughout the entire length of the canal, and in a normal condition yields to diastaltic force of from eight to twelve pounds of pressure.

When rupture takes place it either occurs as a longitudinal laceration of the peritoneum on the convex surface of the bowel or as multiple ruptures from within outward at the mesenteric attachment.

The former result follows rapid and the latter slow inflation.

Hydrogen gas should be preferred to atmospheric air or other gases for purposes of inflation in all cases where this procedure is indicated. Hydrogen gas is devoid of all toxic properties, non-irritating when brought in contact with living tissues, and is rapidly absorbed from the connective tissue spaces and from all the large serous cavities. The escape of air or gas through the ileo-cæcal valve from below upwards is always attended by a blowing or gurgling sound heard most distinctly over the ileo-cæcal region. In gun-shot wounds of the gastro-intestinal canal, insufflation of hydrogen gas enables the surgeon to demonstrate positively the existence of the visceral injury, without incurring the risks and medico-legal responsibility incident to an exploratory laparotomy.

These were the propositions presented by Dr. Senn, and the profession at once assumed a questioning attitude.

The following objections were made to the method: —

First: That it made but little difference whether the wound existed in the intestinal tract or not. That an exploratory laparotomy was indicated in every penetrating wound of the abdomen.

Second: That the test was not infallible, from mechanical obstruction of the intestine or intestinal flexures.

Third: That the contents of the intestine would be blown out into the peritoneal cavity.

Fourth: That a mixture of hydrogen gas and air would result in an explosive compound which might do injury, not alone to the patient, but to the surgeon and assistants.

Fifth: That arseniuretted hydrogen from impure zinc might be generated, and that here lurked a danger, in that poisoning might occur.

Any one who has carefully studied the experimentation that Dr. Senn carried out preliminary to presenting his conclusions, cannot help being impressed by its thoroughness and thoughtfulness.

The problem was presented to me in August, 1888, of whether there was a perforation of the intestinal canal in a stab wound of the abdomen.

The following is a history of the case: —

W. F. D., male, æt. 45. August 25, 1888. At about four o'clock this morning, patient was coming out of his house, when he was stabbed in the right side by an unknown man, who immediately turned and ran away. Patient is a large, well-developed man, with fat, flabby, abdominal walls.

Extending from a point one and one-half inches in front of right anterior superior spine of ilium downwards and inwards is an incised wound about one inch in length, with clean-cut edges; probe enters easily three quarters of an inch; small shreds of clothing in wound; slight hæmorrhage; general condition of patient good; no shock; very little pain. Six hours after accident patient etherized, and hydrogen gas was insufflated into the rectum under gentle pressure; abdomen much distended; lighted match over wound falls to cause any ignition of the gas; a slight cracking was felt over the wound, and a small knuckle of intestine was found caught in the wound. Wound enlarged upwards and downwards to about three and one-half inches; knuckle of intestine drawn out and found to have been slightly wounded at its mesenteric attachment; small ecchymosis about point of injury; a few small blood-clots removed; intestine and wound irrigated, with 1: 10,000 of corrosive sublimate, and returned to abdominal cavity. Wound closed with four deep silk sutures through abdominal wall and peritoneum, and superficial silk sutures.

Dressed with sterilized gauze and sheet-wadding; broad cotton-flannel swathe.

Patient's recovery was uneventful; the distention from the gas passed away within an hour, and his temperature never rose above 99°.

So far as known to the writer there have been seven applications of the hydrogen gas test made to detect wounds of the intestinal canal: —

One case, pistol-shot wound (.38 calibre) of abdomen. Mackie.[3] Two wounds of the stomach, two of the small intestine, and several wounds of the mesentery; all of the wounds detected. Death from septic peritonitis.

Two cases[4] where Fenger applied the test to pistol-shot wounds of the abdomen. The first case is important, for the information obtained by the insufflation of hydrogen negatived a laparotomy, yet six days later Fenger did a laparotomy on this patient and found an abdominal abscess in the coils of the intestine. The patient died eight hours later, and at the autopsy, on separating the adhesions, three more pus cavities were found and general peritonitis. No perforations of the intestines were found, and the inference is that septic peritonitis occurred from failure to properly cleanse the primary bullet wound. Fenger's second case demonstrated satisfactorily the hydrogen test, but ended fatally. Fourteen perforations were found, besides two severe contusions.

One case, pistol-shot wound of the stomach.[5] Patient died on the table from shock and the severity of the injury. Hydrogen test satisfactory.

One case, gun-shot wound (.44 calibre.)[6] Nine perforations of the intestinal canal. Death from shock. All the intestinal wounds found closed at the autopsy.

Two cases by Senn.[7] First case is really remarkable (rifle-shot wound .22 calibre). Twelve perforations were found in the intestines; the last was situated in the deepest portion of the pelvis, and would have doubtless been overlooked had not hydrogen been used. A most desperate case, and yet recovery ensued. Second case, rifle-shot wound (.22 calibre). All the perforations detected and closed. Death from septic peritonitis, which existed at the time of the operation.

Before the use of hydrogen was suggested by Senn we determined the presence of an injury of the intestinal canal by inference, from the symptoms presented by the patient, or by looking at the whole intestinal tract after an exploratory laparotomy. The first method, by inference, was too uncertain to be of any value; while the second, by laparotomy, was attended by considerable risk, not alone from the shock of a prolonged operative procedure, but from the danger of overlooking some of the intestinal wounds.

[7] Med. News, Nov. 10, 1888, p. 528.

Concerning the value and importance of Senn's method there can be but little question. It, however, seemed to the writer that the hydrogen gas test would fail to be generally adopted by the profession, owing to the difficulties attending the securing the gas and the sensational and apparently dangerous way of testing for it, that of lighting the hydrogen, and that consequently Senn's brilliant effort would fall short of its true worth, resulting in a serious loss to surgery.

This led me to see if Senn's method could not be modified so as to combine safety and simplicity in its application and accuracy in its determination.

Senn's reasons for selecting hydrogen gas were apparently: that it is the lightest gas known; that it is innocuous and non-irritating; that its ignition at the seat of the abdominal wound demonstrates its presence, and its burning will asceptic-ize the wound.

We have in the intestines Co_2H, N, CH_4, and SH_2,[8] in varying quantities, according to the diet of the patient; reasoning by analogy, if hydrogen could be used to inflate the intestines, any of the above non-poisonous gases, including air, might be used as well as hydrogen, for all of them are sufficiently diffusible, especially under pressure, to be used for this purpose. From a physiological standpoint there seemed to be no reason why H, O, CO_2, or air might not be used.

Regarding the ignition of the gas at the abdominal wound, this seemed to the writer to be a disadvantage, and the point of antisepticizing the wound is not one of any importance.

I determined, therefore, to try Co_2, O, H, and air. Co_2 is readily obtainable by the action of HCl on marble; H by the action of some acid on Zn; O can be readily obtained at a slight cost in iron cylinders, under pressure; while air is free to all without the asking.

This accessibility of air is a matter of the greatest importance, for the delay incurred in procuring other gases might readily prove fatal to the patient. A series of experiments were instituted and all of the above gases were tried on dogs. I attempted to ascertain —

The best arragement for carrying out rectal insufflation.

To find a more satisfactory gas than hydrogen, and to determine a practicable test for the gas used, either chemical or physical.

To demonstrate the practicability of the gas selected and the tests chosen, upon dogs and other animals.

Method of rectal insufflation. — I should always give an enema before beginning insufflation, for, of course, fæces might readily occlude the lumen of the tube. The apparatus necessary for rectal insufflation is a rubber bag of about sixteen litres capacity, a few feet of rubber tubing, and a glass rectal tube. Useful and almost necessary acessories are a wash bottle and manometer. The apparatus is arranged for use in the following manner: the bag is first inflated with air or gas to be used, and by means of a rubber tube is connected with the wash bottle. The manometer is then connected to the wash bottle by means of a T tube, and to the remaining end of the T is attached a rubber tube bearing the rectal tube.

The tube being introduced a short distance into the rectum, the stop-cock in the bag is carefully opened and the air or gas is allowed to bubble through the wash bottle, when the mercury in the manometer will rise more or less according to the resistance at the end of the rectal tube.

In order to prevent the escape of the air or gas outward, it is necessary to tightly grasp the sphincter about the tube. It is perhaps on this more than on any other point that success or failure depends. The rectal tube should be double, that is, a tube within a tube; this is readily improvised by placing a small piece of glass tubing within a larger one drawn out somewhat to a point and joined together by means of a section of flexible rubber tube. By this means the outflow of air or gas is seldom obstructed. In introducing air or gas into the rectum the following points may be noticed: If there is bubbling in the wash bottle and a proper pressure is indicated by the manometer, air or gas is passing into the intestinal tract. If there is bubbling in the wash bottle and no pressure is indicated by the manometer, or very little, there is leakage about the rectal tube. If there is no bubbling in the wash bottle and a high pressure is indicated by the manometer, there is obstruction to the entrance of air or gas, either by stoppage of the tube by fæces, or by the impinging of the end of the tube against the rectal wall. When the air or gas is going in there is very little question about it, for the inflation proceeds with great regularity.

The length of time that is consumed in insufflation per rectum has varied very greatly, and the above factors have assisted me considerably in carrying out the procedure.

As to the proper pressure to use, Senn has advised from a quarter of a pound to two pounds to the square inch. This pressure in my hands has been sufficient in all cases, and I believe is perfectly safe. Senn states that the inflation must always be made slowly and under steady pressure. I consider both of these points of the greatest importance, and they should be strongly enforced. He further found by experimentation that healthy intestines do not rupture under a pressure of less than eight to twelve pounds.

The writer has found that with a man of about one hundred and fifty pounds weight sitting upon the inflated bag and the end of the rectal tube closed, a pressure of only one and a half pounds to the square inch is indicated. When the air is flowing through the wash bottle at a rate a little faster than one can count the bubbles, the pressure will be about half a pound to the square inch, so that the wash bottle becomes an approximate measure of the pressure.

If necessity demands it, the wash bottle and manometer could be dispensed with, since the greatest pressure which would be obtained under the above conditions is far below that required to produce a rupture of the intestines. Still both wash bottle and manometer should be used when practicable,

[8] The following table shows the proportion in which certain gases occur in the intestinal canal. 1 Ruge. Wien. Sitzungsberichte, 1862, p. 729.

CO^2.....40.50	H 22.20
N.....17.50	SH^2....a trace only
CH^4.....19.77	

as they place the whole procedure on a more accurate basis.

In the absence of a regular gas bag, the surgeon might readily utilize any of the air receptacles that are in common use, such as a football, air life preserver, or air pillow. The point is simply to have an elastic receptacle for the air, that one may secure a steady, uninterrupted pressure in insufflation.

Experiments with gases and air on dogs. — I accepted that the gastro-intestinal canal was permeable to hydrogen, from Senn's experiments.

A small French poodle was etherized, and a stomach tube passed down his œsophagus; this tube was connected with a wash bottle containing a baryta solution. Rectal insufflation of carbonic dioxide was slowly and carefully made, from an eighth to a half of a pound of pressure being used. Carbonic dioxide soon began to appear, bubbling up through the baryta solution and rendering it milky. The dog soon recovered from the effects of the anæsthetic and the carbonic dioxide, and was perfectly well in every respects afterwards.

The insufflation bag was filled with expired air from my own lungs. A water spaniel was etherized and a stomach tube inserted, which was connected with a wash bottle. Under a half of a pound pressure, the air which was insufflated by the rectum soon appeared in the wash bottle, where the bubbling was quite vigorous. The bubbling could be made more or less prominent by increasing the pressure on the inflation bag. This dog soon completely recovered.

A cur collie, sixty pounds, was next insufflated with oxygen after etherization, but for some unknown reason I failed to demonstrate the permeability of the whole canal by the stomach tube. The abdomen being uniformly distended by the oxygen, the collie was twice stabbed with a knife six inches in length and a half an inch blade. The first stab, just to the right of the navel, was only three inches in depth, and apparently did not wound the intestine. The second stab was just to the left of the navel, and six inches in depth. Under gentle pressure on the abdomen the gas came bubbling out of the wound. The slightest pressure on the abdomen or increase of pressure on the bag caused more active bubbling at the wound. A blown-out but glowing match was held in contact with the current of gas bubbling out of the wound, and the match immediately broke into a flame. This was repeated a number of times, the match glowing and subsiding and glowing again. A glass tube which had been drawn to a point was introduced into the wound and the gas was conducted into a wash bottle. Oxygen was again demonstrated as it issued from the wash bottle. The abdomen was then opened, the intestines were found distended, and here and there were found springs of gas bubbling up, coming from the seats of injury.

This bubbling up of the gas, the abdomen being partially filled with hot water, is a very striking phenomenon, and led the investigator at once to the intestinal wounds. No extravasation of fæces. The largest wound was a longitudinal slit one-third of an inch in length, in the ilium.

Brown and white spaniel, etherized. Shot through the abdomen, transversely (.22 calibre). Bullet lodged at a point diametrically opposite, under the skin. Hydrogen insufflation was carried out under an eighth to a half a pound of pressure, until the abdomen was uniformly distended by the gas, but it did not appear at the wound of entrance.

Bullet cut down upon, and a rush of gas heard and the bubbling seen. Hydrogen ignited and burns with a flame three inches in length. Abdomen opened. The pelvis in this case was found filled with blood; the intestines moderately distended. Three lacerated wounds of ilium were found, and one of the vermiform appendix, from which there was a blowing out of fæces. The spleen, left kidney, and aorta had been perforated by the bullet. The hydrogen in this case did not come through the wound of entrance, owing to the obliquity of the track of the bullet, and the shifting of the planes of abdominal muscles during distention.

At this point I became convinced that the physical test for the gases, that of the bubbling and hissing at the wound, was all that was necessary to demonstrate their presence. Just here it may be said that in the application of the chemical tests for the gases in the foregoing cases a little sensationalism is introduced, which, while it may be gratifying to the operator, is entirely unnecessary. For in all my experimentation the first indication of the presence of air or gas has been bubbling and hissing at the wound, and the application of any chemical test has been to identify the individual gas used. This identification of the gas is superfluous, for unless the gastro-intestinal canal is perforated there can be no escape of air or gas. So that the escape of air or gas in any quantity is as marked a phenomenon as any we could have, and is positive evidence of a perforation and a guide to the seat of injury.

I therefore decided to select air as the simplest, safest, and most readily obtainable agent that could be selected for this purpose.

If exception is taken to air as compared with hydrogen on account of its septicity, it may be said that any gas which is selected for use must pass over a tract laden with germs, and hence this objection is not tenable.

Further experimentation was made with air.

A small brown spaniel, after etherization, was shot transversely through the abdomen (.22 calibre). Air insufflated per rectum under a pressure of an eighth to a quarter of a pound pressure. A slight bubbling occurred at the wound of entrance in three minutes, but quickly stopped. Considerable difficulty in preventing the escape of air about the rectal tube. Finally, the wound of entrance was enlarged, when the air came bubbling and hissing out of the peritoneal cavity. Again we had the parietal wound shut off by shifting of the planes of muscles of the abdomen, during distention. A glass tube connected with a wash bottle was introduced through the wound into the peritoneal cavity, when bubbling in the wash bottle could be made more or less vigorous by pressure on the bag. Autopsy: No fæcal extravasation. A double wound through the ilium was found which would have necessitated resection of the intestines.

The perforation in this case could have been demonstrated in from seven to ten minutes had the rectal tube worked well.

A small black poodle was etherized and shot transversely through the abdomen (.22 calibre). Air insufflation; tested at the wounds of entrance and exit of the bullet: negative. Abdomen fully distended. In twelve minutes an incision one and a half inches was made in the linea alba, peritoneum nicked, and immediately there came a hissing and bubbling of air from the peritoneal cavity. Wound at once enlarged to three and a half inches. An unsuccessful attempt was made in this case to save the dog by closing the six intestinal wounds. Operation lasted one hour and forty-two minutes. Six intestinal wounds were secured and three intestinal resections were made by Dr. H. W. Cushing. A great deal of hæmorrhage occurred from the wounded mesenteric vessels. The greatest assistance was rendered by the air insufflation in finding the sites of injury, some of which Dr. Cushing and I felt might readily have been overlooked had it not been for the insufflation of air. Finally, the patency of the whole canal and the security of the intestinal sutures having been tested by air insufflation, the abdomen was closed. The dog survived the operative procedure twelve hours.

At the autopsy, all of the wounds were found tightly closed by "the right angle suture," and the peritoneal cavity free from any effusion.

The rapid subsidence of the intestinal inflation has been a matter of astonishment to the investigator. Not the slightest difficulty has ever been experienced in replacing the intestines within the peritoneal cavity.

The insufflation of air or gas is open to the following objections: —

First, mechanical distention of the patient's abdomen.

Second, the additional apparatus necessary to apply the test.

Third, that laparotomy is always indicated, and that the information obtained by the gas test is superfluous.

Fourth, that the air or gas used may blow out fæces into the peritoneal cavity.

Fifth, that danger exists in the use of gases from their possible poisonous effects, and the possibility of explosion in testing for certain gases.

Conclusions.— That Senn has demonstrated that by a gas test we have a means of obtaining important information, where there is a question whether the gastro-intestinal canal is wounded or not; that the test has been applied to patients, and found to be of great importance; that at present it is unwise to claim for the test infallibility; that it is still *sub judice*, but should receive a careful trial in all cases, that not alone its diagnostic value may be determined but its medico-legal value be accurately placed.

That its position as a test, when obtained, is of great importance; but that, because air or gas does not come out of the wound in the abdominal parietes, does not prove that there may not be a perforation of the intestinal canal.

That in air we have an agent whose presence can be determined by rectal insufflation in punctured wounds of the gastro-intestinal canal; that hydrogen, oxygen, carbon dioxide, and other gases can all be used for this purpose.

That probably in all cases the insufflation of air may be followed by sight and hearing throughout the course of the large intestine, and all observers speak of the gurgling that takes place when the gas passes the ileo-cæcal valve into the small intestine.

That one of the most important applications of the air test will be to determine whether all the wounds in the intestine are closed, to demonstrate the competency of the intestinal sutures, and the permeability of the canal after intestinal suturing or resection.

That contrary to what might naturally be expected, experimentation has thus far demonstrated that air or gas rarely blows fæces into the peritoneal cavity; that, even if it does, the information obtained by the test is of such importance that the objection may be disregarded.

That in punctured wounds of the abdomen (by this is meant perforation of the peritoneal cavity) laparotomy is always indicated; not necessarily to deal with the perforations of the intestinal canal, but that antisepsis may be established and hæmorrhage controlled.

From an operative standpoint I should divide penetrating wounds of the abdomen into two classes. First, where from the use of a knife or from a small bullet the surgeon is in doubt whether the intestinal tract is wounded or not. Second, where it is almost self-evident from the symptoms of the patient, or the character of the projectile used, that the intestines are surely wounded. In the first case, where there is a question whether the intestinal tract is wounded or not, I should insufflate air per rectum, and if it were demonstrated that the intestines were perforated I should proceed with a median laparotomy. If, on the other hand, no evidence is obtained from the air test that the intestinal tract is wounded, I should enlarge the punctured wound, cleanse carefully, and unite the wound. In the second case, where the gastro-intestinal canal is undoubtedly wounded, I should perform a median laparotomy, and then carefully distend the intestines by rectal insufflation of air, keeping the abdomen partially filled with hot water, to prevent shock. The bubbling of air would demonstrate the points of the wounds in the canal, and thus shorten the operative procedure.

After securing each wound of the canal, I should again insufflate air, and in this way I think time could be saved in this serious class of cases.

During this investigation I have received the assistance of a number of gentlemen, and it is my desire to acknowledge my indebtedness to them.

Especially to Mr. G. R. Tucker, chemist and bacteriologist, I desire to express my gratitude for the valuable suggestions and hints that he has made, which have materially assisted in the investigation.

TWO CASES OF LAPAROTOMY FOR PENETRATING WOUNDS OF THE ABDOMEN, WITH REMARKS.[1]

BY ARTHUR T. CABOT, A.M., M.D.

Since Dr. Bull's first case of pistol-shot wound of the intestines awakened interest in the treatment of these injuries, and in view of the constantly increasing list of patients successfully treated in the same manner, the duty of the surgeon to endeavor to repair intestinal injuries made by penetrating weapons or missiles has been almost universally accepted.

The following cases are presented as a contribution to the statistics of this class of injuries.

Case 1. Stab wound of the abdomen: recovery.

Margaret K., who gave her age as about fifty, but who looked much older, entered the Massachusetts General Hospital August 18th, 1886. She was a spare, frail-looking woman. A little more than an hour before entrance she had been attacked by a man with a large pocket-knife. There was a long superficial cut on the right side of her neck, also a cut in the left labium. The abdominal injury was a punctured wound through the outer edge of the rectus muscle on the left side, about an inch below the level of the umbilicus. The patient was pale, as if she had lost considerable blood. She was not suffering much pain.

An immediate exploratory operation was undertaken to see whether the peritoneum was opened, and if so, whether any internal injury had been done. As it was found that the knife had entered the abdominal cavity, the opening was enlarged enough to examine the viscera. One or two ounces of clotted blood lay in front of the intestines; this was sponged out, and a careful examination made of all the coils of intestine lying near the point of puncture. No wound of the intestinal wall was found, and there was no further bleeding as from wounded viscera; the incision was therefore closed. The patient recovered well from the ether, and was reasonably comfortable, with moderate abdominal pain.

August 21st (the third day). The dressing stained through, and on investigation it was found that the stitches, which were of paraffined silk, had slipped their knots, and a little mass of omentum about the size of a child's fist had protruded. Ether was given, and after returning the omentum to the abdominal cavity the wound was firmly sutured. From this time recovery was uninterrupted, and the patient left the hospital well in the early part of September.

In this case the anæmic, feeble condition of the patient gave rise to the fear that hæmorrhage was going on inside the abdomen. In the absence of much blood in the peritoneum it is probable that there had been a greater loss of blood from the external wounds than was thought at the time.

Case 2. Pistol-shot wound of the stomach: laparotomy and suture of the stomach wall; recovery.

Robert E., twenty-one years old, entered the Massachusetts General Hospital the evening of July 3rd, 1888.

Two hours previous to entrance, while standing beside a companion who was handling a revolver, he had been accidentally shot in the abdomen. The distance from the muzzle was about three feet. The ball, of 22 calibre, entered the body two inches above and one inch to the left of the umbilicus. The accident happened about an hour after he had taken a full supper. When seen he was suffering a moderate degree of pain about the wound, and this was increased somewhat by taking a long breath. On palpation there was some tenderness around and above the wound. He had not vomited nor felt any nausea. Laparotomy was advised and at once done.

A vertical incision three inches in length was made so that the bullet opening lay in the middle of it. The transverse colon at once presented in the wound, and was carefully examined for a considerable distance on either side; its mesentery was also inspected, but no wound found. The stomach was then drawn down into view, and at once the bullet hole was seen at about the middle of the anterior wall.

The wound was a simple puncture, which did not gape, and through which there had been no escape of the stomach contents, even though the patient had vomited quite freely while going under the influence of the ether. The hole was turned in, and closed by five interrupted Lembert sutures of fine silk.

The close condition of the wound in the anterior stomach wall, and the absence of extravasation of the stomach contents through it, made it seem wiser not to extensively separate the omental attachments of the organ in order to get at the posterior wall. This would have involved a much larger abdominal incision, and from the apparent line of the bullet it seemed likely that the wound of exit was close to the smaller curvature, where it would have been reached with difficulty, and at the expense of considerable violence of manipulation.

Further search was therefore not attempted, and the abdominal wound was closed.

The patient vomited much after the ether, but otherwise did well.

For three days he took nothing into his stomach but a little water; he then began to take milk and lime water cautiously, and gradually resumed ordinary food.

On the seventh day his bowels acted freely after a senna enema.

He was out of bed on the fifteenth day, and went home at the end of eighteen days.

Since then he has been seen several times, and although he has suffered somewhat from debility, and has not regained fully the flesh that he had before his accident, yet the most careful and thorough examination fails to reveal local trouble anywhere either in the abdomen or chest.

Shortly before the occurrence of my second case Dr. Senn, who has done so much excellent experimental work in the abdominal cavity, suggested a new way of determining whether a penetrating wound of the abdomen opened the alimentary canal or not. This was by the injection into the rectum of hydrogen gas, which, if it escaped through the wound in the abdominal wall, could be ignited, and thus demonstrate beyond doubt the existence of an

[1] Read at the meeting of the Surgical Section of the Suffolk District Medical Society, April 3rd, 1889.

opening somewhere in the intestinal tube. He has shown, by experiment, that the hydrogen gas will thus make its way out; and I believe that until now it has escaped any admixture of oxygen which might form with it an explosive compound and make its ignition a dangerous matter.

Dr. Senn's experiments have shown that the gas finds its way upwards through the whole alimentary canal, and in one case he determined the existence of a perforation of the stomach by the escape of gas through a bullet wound in the lower part of the chest.[2]

Dr. Senn's other work in abdominal and other branches of surgery has been so full of practical suggestions, that a surgeon having a perforating wound of the abdomen, and neglecting to apply a test so highly praised by him, is open to the charge of a disregard of necessary precautions if he cannot show good reasons for his neglect. This must be my excuse for setting forth certain considerations which still deter me from the use of insufflation in these cases. Further experience may show the objections I shall state to be purely theoretical, but until this is demonstrated I shall prefer to treat wounds of the human abdominal cavity in a less experimental way.

Hesitation to use insufflation for the perfection of diagnosis may arise from two fears: one, that it may sometimes fail as a means of testing the condition of the intestines, whether injured or not; and the other, that it may introduce additional dangers into the case.

That it is possible in most cases to demonstrate the existence of a perforation of the intestine in this way has been abundantly shown. Whether the injection of hydrogen furnishes an infallible test may well be doubted. The abdominal wall being made up of separate layers of muscles and other tissues, which shift upon each other with every movement of the body, it must now and then happen that the opening through it is tightly closed, and will not permit the passage outward of gas that has escaped among the intestines. Errors from this cause may generally be avoided by the introduction through the wound of a pair of dressing forceps, a director, or a tube; but with a thick, fat, abdominal wall these measures may fail, especially if the omentum plugs the wound on the inside.

Again, suppose a bullet perforates a coil of intestine that is full of liquid fæces. It is evident that the gas cannot escape through until it has pushed the liquid out before it.

If it is acknowledged that the gas will sometimes not escape even though the intestine is injured, what guidance does the surgeon get from its use in deciding the question whether in a given case to explore the abdomen? In the cases in which the hydrogen gas test succeeds in demonstrating a perforation, we shall certainly do laparotomy.

But what are we to do in the cases in which it does not succeed? Are we then justified in not doing an exploratory operation?

This is the question which the surgeon has to meet; and until it is shown that the fear that in a certain proportion of cases of perforation the test will fail is groundless, he must either do a laparotomy, even in the cases in which hydrogen gas does not issue through the external wound, or he must expect to leave some cases of perforation not operated upon.

Furthermore, it should be remembered that perforation of the intestine is not the only injury wrought by penetrating wounds, which it is the surgeon's duty to rectify. Serious lacerations of the mesenteric or other vessels may exist even without a perforation of the intestine. In both of the cases of intestinal suture reported by Dr. Senn in the Philadelphia *Medical News* of November 10th, 1888, there was profuse bleeding from the mesenteric veins, and the ligation of these was one of the important benefits of the operation.

It is the strong chance of such accidents as this, and the feeling that there will be cases in which perforations of the intestines or stomach will escape the hydrogen gas test, that make the writer feel that in the cases where no hydrogen emerges from the outer wound the surgeon would still not be justified in foregoing an exploratory operation.

If this feeling is borne out by facts, and an exploration is called for whether the hydrogen test succeeds or not, it is obviously a waste of time to apply the test, even supposing the injection of the gas to be a harmless proceeding. But is this last supposition correct?

Dr. Senn says that the gas is aseptic and therefore innocuous. Does he mean by this that the gas, after passing through many feet of intestine, enters the peritoneal cavity in an aseptic condition? And what is to be said of the intestinal contents that the gas drives along with it? They are certainly not aseptic, and it is therefore evident that there is a strong possibility that the injection of gas may add to the dangers of a given case, and should not be lightly used.

What has been said up to this point applies only to the use of the gas for diagnostic purposes before an incision has been made.

There is another use of gaseous insufflation to which Dr. Senn calls attention in the paper already referred to, which may be of great service.

After closing all of the perforations that he could find, he again injected the hydrogen into the rectum and it at once began to bubble up from the pelvis. Following down the sigmoid flexure, and compressing it at different points, the gas still escaped until he reached the rectum, where he found and closed a last wound.

Continuing the injection, he saw the gas go up past the openings that he had closed, and, finally, stopping the injection to avoid the too great distention of the bowels, he pressed the gas already introduced upwards from coil to coil until he reached the duodenum and stomach, without finding any more perforations.

This application of the insufflation, after all of the openings that can be readily found have been closed, seems to be of undoubted value. It enables the surgeon to make a quick but thorough exploration of the bowels with the least possible amount of handling. The gas escapes at once into the air, and does not carry impurities throughout the abdominal cavity, and if it carries with it liquid fæces their escape is at once perceived and they are quickly removed by irrigation.

[2] In this case the injection was made directly into the stomach.

For this exploration it would seem that air would be equally good with hydrogen gas.

The suggestion of this procedure adds one more to the capital points in abdominal surgery for which we are indebted to Dr. Senn.

To return now to the consideration of the cases reported. In both of them laparotomy was performed at once when they were first seen.

This practice of immediate laparotomy, without waiting for convincing symptoms of serious intra-abdominal lesion, seemed wise, for the following reasons: —

First: It was felt that the enlargement of the penetrating wound through the abdominal wall added little or nothing to the severity of the injury, and would give the opportunity to discover and repair any lesion of the intestines or other abdominal contents before the occurrence of peritoneal inflammation. The absence of danger in a simple incision into the abdomen is generally recognized.

Secondly: We know that symptoms are often very poor guides to an appreciation of the severity of intra-peritoneal injuries, and if we wait until the patient's condition demands an operation, we shall often find that a serious inflammatory condition has arisen, which we are powerless to stop, even though we may succeed in closing the intestinal wound that gave rise to it.

The cases are as yet too few to determine the ratio of the increased danger in delayed operations, but experiences are not wanting to show that it is very large.

Thirdly: In the event of any considerable vessel being injured it is, of course, important to stop the bleeding early before the patient is seriously exhausted. Here again, if we wait until the symptoms of internal hæmorrhage are unmistakable, we shall run a serious risk of letting the patient slip into a condition from which he cannot be recovered.

In view of these considerations it seemed to the writer, and he still thinks it a good rule in practice, that — in a case of penetrating wound of the abdomen, made by a sharp weapon or by gun-shot — the wound should be followed carefully down until the operator is convinced that it enters the abdominal cavity. When this is established the peritoneum should be opened with enough freedom to allow of a sufficient inspection of the abdominal contents, and for the repair of any injury found.

It seems probable that by this immediate operation cases will be saved which would be lost if time were given for the peritoneum to inflame or for serious loss of blood to occur; whereas with proper care in making a clean, aseptic operation the surgeon will rarely, if ever, feel that he has added to his patient's risk by the exploration.

TWO CASES OF PENETRATING WOUND OF THE ABDOMEN.

TREATMENT BY LAPAROTOMY.[1]

BY F. B. HARRINGTON, M.D.

Case I. Knife wound of the abdomen with protrusion of the omentum: laparotomy; recovery.

[1] Read at meeting of Surgical Section of Suffolk District Medical Society, April 3rd, 1889.

A. D., thirteen years old, came to the Massachusetts General Hospital, September 10th, 1887. He was stabbed in the abdomen with a knife, about midway between the umbilicus and pubes, and two inches to the left of the median line. The wound was about one inch in length. Through this wound protruded a mass of omentum, completely plugging it. The wound was enlarged to about double its size. This allowed an easy reduction of the omentum, and gave an opportunity to inspect the intestines lying directly beneath the incision. The omentum, when returned to the abdominal cavity, began to bleed. The constriction made by the edge of the incision had controlled the bleeding until this constriction was removed. The bleeding points were tied. No injury to the intestines was found, and nothing pointing to such injury was seen. The patient was about the ward on the eighteenth day, the wound having entirely healed.

Case II. Pistol wound of the abdomen: laparotomy; death.

W. G., a teamster, twenty-four years old, was brought to the Massachusetts General Hospital. August 6th, 1888, at about 6.30 P.M., pulse 80, temperature 100.8°, respiration 30. He had been shot one-half an hour before. Examination showed a strong, vigorous man. A bullet wound in left chest between first and second ribs, three fingers-breadth from the clavicle's sternal end. There was a bullet wound one inch below the umbilicus and two or three fingers-breadth from umbilicus in left side. There was also a bullet wound on the inner side of the femoral vessels in Scarpa's triangle. No bleeding of any account from either wound. Wounds not probed. The urine was drawn by catheter and found to be bloody, but there were no clots. Spit some blood from the throat. No cough. No pain in chest. Abdomen tender. Pain in small of back. The flanks are flat on percussion, otherwise the abdomen was tympanitic. Morphia and brandy were given.

At 8.30 the urine was more bloody. The pulse had become rapid. The patient seemed to be sinking from loss of blood. It seemed best to attempt a laparotomy. Two quarts of blood mixed with intestinal contents were evacuated. Blood and intestinal contents were flowing into the abdominal cavity freely. Three holes in the small intestine and two lacerated wounds of the intestine were sewed up with silk. The abdomen was washed out with warm water. The posterior course of the bullet was not determined. It was thought that it might have cut the ureter or have entered the kidney. The patient rallied slightly, but died at 12.20 in the morning. On autopsy it was found that the left kidney had been pierced by the bullet which had injured the intestines. There was considerable hæmorrhage into the perinephritic tissues. The abdominal cavity, upon removing the intestines, was found to be perfectly clean, notwithstanding the large amount of blood and fæces which it had contained before washing. No other intestinal wounds were found. The bullet wound of the chest passed through the apex of the lung. No wound of the intestines had been overlooked. Insufflation was not used.

CREASOTE IN CERTAIN GASTRIC DISTURBANCES.

BY JOHN A. JEFFRIES, M.D.

CREASOTE has been used and recommended in troubles of the stomach for many years, but has of late, it seems to the writer, fallen into desuetude. Yet it is an efficacious remedy in a class of common stomach troubles, which if not marked by any serious pathological changes are fraught with annoyance and distress to the patient.

A patient comes with a complaint of distress after meals and acid taste in the mouth, the belching of wind, and perhaps disturbed action of the bowels, and general discomfort or sense of weakness, is out of sorts with himself and the world, and may even suffer from irregular vomiting.

The modern specialist on the stomach passes the stomach tube after a test breakfast, and finds perhaps quantitative changes in the constituents of the gastric juice and an increase in the amount of mucus. The diagnosis may read as an increase or diminution in the acids or as simple fermentation. The treatment will begin with washing out the stomach, and in most cases, according to my experience, results in a cure.

The trouble is that though washing out the stomach is not difficult it is highly objectionable to the average patient, and in a hospital out-patient service is out of the question on the score of time.

It is desirable, therefore, to have as many strings to our bow in the shape of drugs as possible, and creasote is a good one. It was formerly used with carbolic acid in vomiting, and is thus recommended by Barthelow. Starting with Barthelow's recommendation I began the use of the two drugs combined, in vomiting, and got good results, but fearing the carbolic acid shortly left it out. From this the use of the drug was extended to the various indigestions, and it is my object to present a short analysis of the cases in which I found it useful or useless.

First, it is a good sedative in vomiting where the cause is general and uncontrollable, or unknown, and is thus mentioned in most of the books on therapeutics. Beside this it is of use in vomiting induced by fermentation, and thus comes into play in the summer gastro-intestinal trouble of infants, as the following case illustrates: —

July 2, 1887. M. K., six months; breast fed; cutting a tooth. Seized this morning with diarrhœa and vomiting, the ejected matter being almost clear water with a few flocculi. Eyes sunken, fontanel the same; abdomen drawn in; body hot, temperature in the rectum 101°, limbs cold; pulse small, rapid, could not be accurately counted.

The treatment consisted in a drop of creasote, five grains of bismuth in cinnamon water, every three hours at first, and scalded milk with brandy in ounce doses between. The milk was given as being the best food I thought the child would get. The vomiting stopped for a time after the first dose and ceased during the afternoon. On the 3rd there was less diarrhœa and no vomiting. On the 4th neither vomiting nor diarrhœa. The next day slight green diarrhœa began, but on the 9th my notes record the child as well and the tooth cut.

A score of other cases could be given where vomiting in infancy has ceased after the administration of creasote, but I have but one other which approached the rice-water ejecta of the above. Water has often been vomited, but as often questioning has shown that the infant has recently had a drink.

The diarrhœa usually coexisting in these cases has not seemed to be influenced, though promptly ceasing with the use of other drugs.

In adults the symptoms are more variable, as also the results. The following cases are selected from a number as illustrating the differences in both: —

CASE II. August 28th. Male, forty-one years, married. Complained of pain, tenderness, and stiffness in left lumbar region; pain and tenderness over the ensiform cartilage, and an "empty acid heaving;" bowels regular. No other symptoms found. Two drops of creasote were ordered three times a day in gum arabic and water.

August 31st. Stomach decidedly better; pain the same.

CASE III. September 6th. Male, forty-seven years, married. Complained of weakness of legs and indigestion; hands and legs weak; grip, right 56, left 64; anæsthesia and numbness below the knees; slight general trembling; slight but distinct Romberg's symptom; pupil reactions normal; knee-jerk the same; no tenderness of nerves. No signs in the thorax, urine normal. Distress after eating, followed by yawning, belching, and an acid taste in the mouth. The only drug given which could affect the stomach was creasote. In two days the distress and belching ceased, and the creasote was stopped. In four days the trouble came back; creasote was again given for a longer interval, and the trouble did not come back.

CASE IV. September 22nd. Female, twenty-two years, single. Seven months ago both legs began to prickle and tingle; pain in the head, and frequent nose-bleed. For the last three weeks it has been difficult to stand. Now patient appears in good condition, but will scarcely try to stand still and walks in a weak, irregular way; marked Romberg's symptom; no other symptoms; all the ordinary reflexes normal.

October 5th. Walks better; can stand with eyes closed; tongue coated, belching, head light, sour taste in the mouth. Creasote in two-drop doses three times a day.

October 11. Stomach symptoms gone. In the course of a few weeks the nerve symptom also vanished under appropriate treatment.

CASE V. August 21st. Female, forty-two years, married. Twelve years ago had typhoid fever, and has never been the same since. For two years has been in much the present state. Numbness and burning of hands and feet, hands weak; vertigo, frontal headache; pulse 80, weak; temperature 98.4°; no appetite for breakfast, sense of nausea, frequent belching, acid taste in the mouth, with yawning. Urine normal. Creasote in two-drop doses and the faradic brush.

August 25th. Gas, acid taste, and nausea gone.

Slight burning in stomach. Creasote stopped. During the next month had a return of the stomach trouble, and took creasote at her own request with a good result.

CASE VI. July 18th. Female, thirty-eight years, married. Troubled with heavy sensation in stomach after eating, acid eructations, loss of appetite, and pain along fifth and sixth left ribs and over the left triceps. Constipation; reflexes irritable. Treatment, cascara sagrada and creasote, two drops before meals.

July 25th. Wind, sour taste, and pain gone, bowels more regular.

CASE VII. December 21st. Male, thirty years, married. An epileptic. Complains of nausea and wind; no acid taste. Creasote.

January 26th. Nausea and wind gone.

CASE VIII. November 17th. Male, twenty-four years, single. Complains of heavy feeling, nausea, belching, sour taste in mouth, headache, and dizziness in the forehead. Gave creasote.

November 27th. Now only constipation and wind in stomach. Gave cascara.

December 18th. Bowels regular, no symptoms except the wind.

CASE IX. September 12th. Female, forty years, married. Numb hands, pain in the back on waking, also from pit of stomach to shoulder-blade. Wind if stomach empty, sour or at times bitter taste, tongue slightly coated, attacks ushered in by yawning. Mouth sometimes waters, but denies nausea. Constipation. In this case creasote and cascara did no good.

CASE X. October 11th. Female, married, forty-eight years. Complains of pain in head, especially over eyes, vertigo, belching, weight in stomach, nausea, and bad taste in the mouth. Gave creasote, and the symptoms vanished in the course of a week.

The above class of cases in which creasote has proved of service are mostly characterized by more or less nausea, or some of the other prodromata of vomiting, as yawning, the evolution of gas in the stomach, and an acid taste after eating. When the wind or acid taste is absent I have had more failures, and in cases like Number IX., where the wind was only between meals, no success. In some of the cases all the symptoms but the wind have vanished.

The exact nature of the morbid processes in these cases I do not know. The use of creasote was begun under the belief that the acid taste and wind pointed to fermentation, and creasote is given as a fair antiseptic. My own experiments, however, show that creasote is a much weaker germicide than ordinarily stated. Again, in certain cases the wind continued though the other symptoms vanished, showing that the symptoms were not all closely connected.

Besides its weak germicidal powers creasote possesses an astringent effect on mucous membranes which is not to be lost sight of. In the same class of cases salicylate of soda has not been of as much service in my hands.

Where a close observation of the drug is not desired, unless constipation exists, the creasote has been usually administered with bismuth in water, the bismuth in some way seeming to take the former up and make a presentable mixture.

Clinical Department.

REPORT OF A CASE OF ACUTE HÆMORRHAGIC GASTRIC ULCER.

BY C. M. HAY, M.D.,

Assistant Physician to the State Insane Asylum, Morristown, N. J., late Resident Physician at University Hospital, Philadelphia.

THE following case came under my observation on February 1, 1889, and was interesting in several respects. Mrs. T., age 23, one child, always healthy up to her present illness, normal weight 120 pounds, habits excellent, physique and general health exceptionally good. On the above date she began to have pain in the epigastrium, which she described as "boring deep, and aching," but which occasionally became more severe, and then would shoot to the back and up between her shoulder blades. This pain was not constant, and was induced by eating. On the following day she began to vomit after taking food, and attacks of pain were more frequent and severe, while a slight febrile reaction was added, which, by evening, was 102° F. Examination now revealed a normal condition of the heart and lungs. The hepatic and splenic dulness was of normal extent, and in the epigastrium, about two inches below the ensiform appendix, a circumscribed area of extreme tenderness on pressure was found. This was of the size of two silver dollars, and extended more to the right than to the left of the median line. There was no evidence of tumor, and percussion gave the ordinary gastric tympany. Examination of the remainder of the abdomen was negative, as was also that of the urine, uterus, ovaries, and menstrual functions. On the third day, after taking some milk, she had a copious hæmatemesis, losing fully ten ounces of liquid arterial blood, containing some loose coagula. This was preceded and accompanied by great pain in the abdomen, followed by nausea, and its occurrence gave relief. On the fourth day a similar hæmorrhage occurred spontaneously, the patient losing somewhat less blood, which was darker in color, and more coagulated than the first. During this time, even the smallest amount of liquid was rejected by the stomach, and considerable altered blood was passed through a single movement of the bowels, which had been obstinately constipated from the beginning of her illness. Slight pyrexia continued, with rapid and excited cardiac action. Examination of the epigastrium now revealed some enlargement of the area of tenderness, but no other symptoms. At 5 A.M., on the fifth day, on making a sudden movement of the body, she was seized with pain in the epigastrium, and in about fifteen minutes she vomited about ten ounces of unaltered blood. Fifteen minutes later I found her exhibiting signs of hæmorrhage, and there was extreme muscular weakness, ringing in the ears, complaints that "she could not see," great rapidity of the heart's action, with pain and fullness in the region of the stomach, and great mental perturbation. These symptoms were followed in a few minutes by nausea, when she suddenly partially rose up and vomited nearly a quart of dark-colored liquid blood, containing loose coagula, and fell back in syncope. Reaction occurred very slowly, and dur-

ing the ensuing week the patient continued in a state of extreme weakness, with considerable anæmic fever, attended by thirst, dimness of vision, murmurs at the cardiac orifices and great vessels, and all the other subjective and objective signs of great anæmia. Blood was again found on three occasions in the stools, and small quantities of coffee-ground material were vomited for several days, while the epigastric pain and tenderness remained the same. From this time the patient slowly improved, and by February 15th had gained blood and strength; pain and tenderness were somewhat less, and she had only occasional attacks of vomiting, while the fever had practically disappeared. By February 28th light liquids could be retained, although there was a decided tendency towards emesis. At this point in the case it was very interesting to observe the gradual, progressive diminution of the area of tenderness, with the corresponding lessening of pain. From this time the patient improved more rapidly.

The case was complicated by herpetic tonsillitis on March 3rd, which, however, subsided quickly in three days. On March 20th light, digestible solids were first allowed, and on the 27th she was allowed to sit up in a chair for the first time. At this time her pain was entirely gone, and the area of tenderness, which had been slowly getting smaller and smaller, was now a mere point, with difficulty found by the finger. The patient (who had lost twenty-five pounds in weight) now gained rapidly, until by April 20th her weight was one hundred and fifteen pounds, with no return of any previous symptoms, while her tongue, which had been at first coated, and, lately, fissured and flabby, was again normal in appearance. Examination failed to reveal any tenderness in the epigastrium, and she was permitted to resume her ordinary duties.

The treatment of this case consisted, during the period of the hæmorrhages, in full doses of morphia and ergotine, hypodermically, small pieces of ice by the mouth, and an ice bag over the epigastrium at the time of the largest hæmorrhage. During the following twelve days no food was allowed by the mouth, and nutritious enemata were exclusively relied upon to support the patient. Small quantities of ice, sufficient to allay thirst, were given by the mouth. For the next ten days small amounts of diluted milk and animal broths, with the enemata, constituted her sole diet. During this time she also received a pill of nitrate of silver, in combination with the extract of opium. On two occasions, when emesis threatened, all food was stopped until the stomach was again entirely retentive. Rectal injections were discontinued on February 28th, and Blaud's pill was then added to her treatment, while a liquid diet was enforced until March 20th, when all local symptoms disappeared, and murmurs were no longer heard over the præcordia.

The diagnosis of this case seems to be very clear. The general blood conditions which at times are causes of such hæmorrhages can be excluded from this case by the previously healthy condition of the patient and by her family history; while the normal condition throughout the case of lungs, liver, uterus, and spleen proves the absence of disease of any of these organs as a causative factor. The course and termination of the case exclude aneurism or cancer, while, with the absence of ascites, obstruction to the portal circulation or vein cannot be considered. The symptoms clearly point to a local gastric lesion, and they were confirmed by physical examination of the epigastrium. Traumatism in all its forms can be excluded, as can also disease of the gastric blood-vessels, varices of the veins, and passive congestion of the stomach, by the age of the patient and the healthy condition of the circulatory system throughout the body; while, as ulcer is by far the most frequent cause of such massive hæmorrhages from the stomach, it may be safely assumed that such was the lesion in this patient. The case is interesting from its acute commencement, the size and number of the resulting hæmorrhages, its definite course and termination by recovery, and also from the standpoint of etiology and treatment. It is comparatively rare that we have an opportunity of seeing a gastric ulcer develop in the way that this one did. That the ulcer was not of the chronic form, which had been previously latent, is sufficiently proved by the perfect health which she enjoyed up to the time of the present illness, and also by the perfect recovery which the patient has since made. The rapidity of its formation and the appearance of all the symptoms is worthy of note, the first hæmorrhage occurring just three days after the first symptoms of gastric trouble appeared, while the size of the hæmorrhages proved nearly fatal. The manner in which the patient rallied and slowly recovered; the gradual disappearance of the epigastric pain and tenderness, together with her present good health and gain in weight, seem to indicate the complete healing of the ulcer. Why this woman should have had a gastric ulcer I cannot conjecture. She was under the operation of none of the ordinary causes. Her age, sex, and the fact that she habitually wore tight corsets are all the predisposing causes that I have been able to discover. Embolism or thrombosis of one of the gastric vessels in the posterior wall of the stomach would perhaps best account for the symptoms, but there is no organic valvular disease of the heart or any other discoverable cause of such an occurrence. In conclusion, I may say that it would appear that this case was not of the chronic variety of gastric ulcer, but that it was that rarer, acute, hæmorrhagic form, which luckily did not terminate by fatal hæmorrhage or perforation, and did not become chronic, but rapidly healed.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

GEORGE H. MONKS, M.D., SECRETARY.

MEETING Wednesday evening, April 3rd, 1889. DR. E. H. BRADFORD in the chair.

DR. ROYAL WHITMAN showed patients illustrating his

TREATMENT OF FLAT-FOOT,

and spoke as follows: —

"The treatment of the cases of flat-foot which have come under my observation has been conducted on the following principles: —

The affection is the result of overstrain, and is essentially a dislocation of the bones of the foot, with the usual accompaniments of a dislocation in varying degree. Thus muscular spasm, contraction, atrophy, deformities of bones, etc., are considered as results and not as causes. The remedy must therefore be (1) in a reduction of the dislocation; (2) in supporting the foot in its corrected position by a brace; when, with suitable exercises, and by an avoidance of the causes which produced the affection, the weakened, stretched, and displaced muscles and ligaments may regain their strength, and a cure ultimately result.

One or two points in the above are considered of particular importance. 1st, that flat-foot is the result of overstrain. The feet, as any other part of the body, may be essentially weak, but, unlike other parts, they are subjected to constant weight and strain under unfavorable mechanical conditions. 1st, because they are compressed in improper shoes; 2nd, because of the custom of turning out the toes to an excessive degree in walking and standing, — a position which throws the greatest strain on the weakest part. It is of the utmost importance, both in the prevention and treatment of flat-foot, that a proper walk should be insisted upon; that the feet when in use should be nearly or quite parallel to each other, in order that the weight of the body may be thrown on and over the toes, and not inside them. Thus each correct step may be made an exercise to strengthen a weak foot, while each improper one has a tendency to aggravate the existing deformity. The brace which has been used exclusively during the past year has already been described; theoretically it has the merits of accuracy of adjustment, as it is in every case moulded on a cast of the foot in its corrected position; of simplicity and inoffensiveness (as its presence is not apparent); of being equally applicable to all cases, in any class of society or grade of intelligence, and that it does not interfere with the normal movements of the foot. Practically its value has been proved in a very large number of cases.

It is perhaps unnecessary to remind you that flat-foot is often a very painful and disabling affection, and that it is important to recognize it in the early stages, before permanent changes have taken place. Its nature recognized, I know of no affection where the results of treatment are so immediate and satisfactory. The more severe the symptoms, the more rapid and efficient the remedy."

The Chairman spoke in the highest terms of Dr. Whitman's method of treatment, and declared that he had often had the opportunity of observing its good results.

Dr. F. B. Harrington said: I consider Dr. Whitman's treatment a very valuable and marked advance in the treatment of flat-foot. The case which I sent to Dr. Whitman was a very severe one, and the improvement shown is remarkable. The rectifying the deformity under ether and the fixation of the foot in a corrected position seems to me the most essential part of the treatment of the severe cases. I have found the study of these cases extremely interesting, and am more and more convinced of the value of Dr. Whitman's treatment.

Dr. Whitman called attention to the frequency of flat-foot, and to the fact that many of such cases are long treated for rheumatism without relief, when a properly applied plate would relieve them at once. He regretted that all medical men were not a little more careful in diagnosis.

Dr. A. T. Cabot also spoke of the importance of the early recognition of the true condition; and called attention to the pain running up the calf, and the tenderness particularly over the inner arch as being aids in diagnosis where the deformity is not marked. In just such cases a good plate would give great relief.

The Chairman related the case of a young man who had been told by a physician that he had disease of the spinal cord; but it was simply a case of flat-foot, which was some time later relieved at once by plates like those described by Dr. Whitman.

In reply to a question Dr. Whitman explained how the mould of the foot was taken. The patient sits in a chair and rests his foot upon its outer border in a box filled with soft plaster, which is placed upon another chair. The plaster is built up about the foot to its middle line. The inner (now upper) side of the foot is then covered with plaster, and the mould is thus made of two lateral halves. A cast of the toes is unimportant, and that part of the foot can be neglected, as it has nothing whatever to do with the shape of the plate to be fitted.

Dr. A. T. Cabot reported

TWO CASES OF LAPAROTOMY FOR PENETRATING WOUNDS OF THE ABDOMEN,[1]

the one case being a stab with a jack-knife, and the other an accidental pistol-shot wound.

Dr. H. L. Burrell read a communication on

A CONSIDERATION OF THE USES OF GASES IN PENETRATING WOUNDS OF THE ABDOMEN,[2]

which he illustrated by extremely interesting experiments on dogs, using hydrogen, oxygen, and air to demonstrate the presence of gastro-intestinal injuries.

Dr. F. B. Harrington reported

TWO CASES OF PENETRATING WOUND OF THE ABDOMEN; TREATMENT BY LAPAROTOMY.[3]

The Chairman related a case of his own, where the patient was stabbed in the abdomen. The wound was enlarged, but the intestine was found to be only bruised, though the bleeding was considerable. The peritoneum was washed out with hot water and the wound sewed up. The patient died of septicæmia. The fact that the case was a medico-legal one somewhat complicated affairs. The decision given was that the infection was probably due to the assailant's knife rather than to the surgical operation, since in the latter efforts had been made to keep everything aseptic.

Dr. M. H. Richardson called to mind the fatality which statistics give to cases of penetrating wounds of the abdomen. He thought that in the war the mortality rate was about 90 per cent. He could not, however, express much confidence in the insufflation method, so far as he could judge from his reading on the subject and from his own somewhat limited experience. It had always seemed to him that inflation of the bowels would interfere

[1] See page 81 of this Journal.
[2] See page 77 of this Journal.
[3] See page 83 of this Journal.

with any subsequent examination in case laparotomy was done, though perhaps this difficulty was an imaginary one. He felt, however, quite sure that the escape of fæces through an intestinal wound into the peritoneal cavity was a real danger, and he had seen it happen, and that in his only case. His idea seemed to be that if a laparotomy is to be done any way, there is no use of insufflation to begin with. The method may, however, be of some use after all apparent perforations have been sewn up, to make sure that all have been found.

DR. H. W. CUSHING said: I have been exceedingly interested in Dr. Burrell's experiments; and they have been to me a very instructive and valuable demonstration of this subject. Insufflation has apparently two rôles: first, to indicate the existence of an intestinal perforation; second, to locate it. In estimating its value, penetrating wounds of the abdomen must be considered in two classes: stab wounds, and bullet wounds. In stab wounds the possibility of the hollow abdominal viscera escaping injury is considerable. If there is no perforation one of the chief indications for an exploratory laparotomy is absent; and the victim is spared a serious, at times dangerous, operation. Here, therefore, insufflation as a diagnostic aid is of great value; and, as a direct means of recognizing intestinal laceration, of vital importance to the patient. With bullet wounds, on the contrary, the possibility of the intestine escaping uninjured is very small. In no case, according to my own observation, has the intestine escaped when the ball has entered the abdominal cavity, and the laceration in some instances has been to a fearful extent. Hence, in this class, the value of insufflation as an agent to indicate perforation is not of so great importance. The surgeon will probably, unless he has some strong indication to the contrary, open the abdomen at once in every case. Under such circumstances, however, as a rapid means of locating the site of the perforation it has proved a most efficient aid, and of equal importance is its power to demonstrate to the surgeon the important fact that he has closed all the wounds. It unquestionably shortens these operations and renders unnecessary the extensive, prolonged exploration and manipulation of the abdominal viscera so productive of excessive shock. In some of Dr. Burrell's experiments I am confident that some of the wounds would have remained undiscovered without the aid of insufflation. In regard to the technique, the method of using air which he recommends is much more satisfactory and practical than the "Senn" method. It requires no especial preparation or complicated apparatus. The demonstration of its escape from the abdominal wound is unnecessary: it consumes time, and is occasionally difficult, if not impossible, even where perforations exist. The practical points for the surgeon are: The distention of the abdomen, without which, of course, there can be no insufflation. When this has been accomplished his efforts must be to ascertain if the air is in the peritoneal cavity as well as in the intestine. The surest and most rapid way to demonstrate this is to slightly nick the peritoneum. The hiss of the escaping air at once shows its site. Also the bubbling of fluids in the wound. If this does not occur the air is confined to the intestinal canal, which is in all probability intact. In none of the cases I have seen has the distention of the intestines been an impediment to the operator, or prolonged the operation. Extreme distention is not necessary to demonstrate the perforations, and the subsequent rapid collapse of the gut prevents any such complication.

DR. J. R. CHADWICK was inclined to think that Senn's method was not reliable before laparotomy was done; but that it might be of great use, when the abdomen was laid open, in finding the perforations and in making sure that those already stitched were tight. He thought the introduction of an antiseptic fluid into the abdominal cavity would be of advantage, not only to float up the intestines, but to detect hæmorrhage by the tingeing of the fluid as it ran out.

DR. HARRINGTON said that he should be inclined to do a laparotomy in most cases of penetrating wounds, and if insufflation were used it would only be after the abdomen was opened.

THE CHAIRMAN wished then to know if it was the sense of the meeting that in all fresh cases of penetrating wounds of the abdomen laparotomy should be done.

Several gentlemen present objected to so broad a statement, and were inclined to think that in many fresh cases no exploration whatever should be made.

EXHIBITION OF SPECIMENS.

Two specimens sent by DR. JOHN HOMANS were then shown. One was a fibroid of the uterus, weighing fifteen pounds, which was removed on March 28th. Present condition of patient very satisfactory.

The other specimen was two tubes and ovaries, which had been with the greatest possible difficulty "dug out" of the pelvis of a single woman of twenty-five, by laparotomy.

THE CHAIRMAN showed an enlarged prepatellar bursa, recently removed by him; also a sarcoma of the buttock.

AMERICAN CLIMATOLOGICAL ASSOCIATION.

SIXTH ANNUAL MEETING, BOSTON.

Second Day — Tuesday, June 25, 1889.[1]

DR. R. G. CURTIN, of Philadelphia, read a paper on

THE CLIMATOLOGY OF HÆMOPTYSIS IN CHRONIC LUNG DISEASES FROM AN ETIOLOGICAL AND THERAPEUTIC STANDPOINT.

In glancing over the field we are confronted by so many and varied influences of climate at work, both in causing and preventing hæmoptysis, that the subject will be best considered by taking up each factor separately, and discussing it as to its bearings, and the symptoms under consideration, and its debilitating result. If the chronic lung disease is removed by climate, this, a mere symptom, is necessarily ended. We must be careful not to magnify hæmoptysis, a mere symptom, into the formation of a distinct disease.

First, I will give a brief summary of the more immediate causes of bleeding from the lungs in chronic pulmonary diseases. We are liable to hæmorrhages from the lungs, caused —

[1] Concluded from page 70.

1st. By capillary congestion of the bronchial mucous membrane.

2nd. By congestion of the parenchyma of the lungs.

3rd. From erosion of blood-vessels from the ulcerative process.

4th. Pr. disposition from condition of the blood, as in hæmophilia.

5th. Atmospheric influences.

6th. Nervous influences.

The hæmorrhage may be bronchial, capillary, arterial, or venous. The principal climatic conditions affecting hæmoptysis are included under the following heads: Heat, moisture, and altitude, asepsis, rarefaction of air.

For syphilitic phthisis, denser air and increased arterial pressure are, I believe, beneficial in a curative way, as shown in my paper read before this society two years ago in Baltimore.

In cold air the tissues and blood-vessels contract, especially the capillaries, driving the blood from the periphery towards the centre, but not with sufficient force to cause a dangerous internal congestion. It has a beneficial effect upon the appetite, and favors assimilation and strengthens the nervous system, imparting internal vigor.

Warm air. The effect of continued warm air is to cause a debilitated and relaxed condition of the tissues and blood-vessels, which would in itself tend to the exudation of blood from the diseased tissue of the lungs.

Sunshine. A patient living in the crowded city, shut between walls, and with perhaps many cloudy days, is subject to depressing influences. Remove a person so situated to a place with much sunshine and to out-door life and he will be benefited by such a change.

Each case should be carefully studied in all its phases before deciding upon a change of residence.

Dr. Edward O. Otis, of Boston, read a paper on

PSYCHOLOGICAL FACTORS IN SELECTING A CLIMATE FOR INVALIDS.

To best adapt the remedy, be it climatic or medicinal, to the case in hand, the psychological side of the question, as well as the physiological and path ological, must have its due consideration. From a psychological point of view we ought, it seems to me, to consider, 1st, the temperament and mental disposition. 2nd. Previous habits and mode of life. 3rd. The amount of physical activity the patient has been accustomed to. 4th. The matter of domestic ties. 5th. Is the patient to be placed in an environment of invalidism, where he will have his malady suggested to him continually by seeing others sick and dying with it about him? 6th. The age of the individual.

An analysis of that bundle of peculiarities which constitutes what we call one's temperament is often an easy matter, yet it ought to have careful study when a change of climate is under advisement. One's natural disposition, to a great extent, shapes his way of life and determines his habits. The tastes of the patient play a not insignificant rôle in his physical condition and well-being, and a disregard of them may vitiate the good results hoped for by a climatic change. The matter of length of residence in the climate selected depends upon many considerations, principally upon the kind, character, and extent of the disease.

Of course, individuals vary much in the manner of adapting themselves to circumstances. Where, however, the longing for the dear ones at home is extreme and continual, a spot nearer home, with a climate less intrinsically ideal for the disease, but affording easy communication with home and friends, may accomplish better results, as, for instance, Sharon in this State or Lakewood in New Jersey.

An environment of invalidism is almost unavoidable in most of the well-known health resorts. Besides these injurious influences, in other respects mainly it is in many ways unfavorable. To be sure, climate in a way makes us all akin, but in thinking of and helping an unfortunate brother our mind is diverted from our own misery to our benefit. On the other hand, however, to be amongst many others of the same disease as our own in its varying degrees and phases must often react unfavorably on our own disease. Our disease is kept constantly before us, and I have noticed that the majority of invalids seem morbidly eager to discuss their own symptoms and watch and note the simplest variations in their own condition. I am convinced that this seems to be a serious objection to such health resorts as are exclusively devoted to invalids and to those suffering from the same disease. Is not the objection all the greater to sanitaria where many invalids are under one roof, particularly if the disease is phthisis?

Certain it is that the influence of an environment of strong health, and, secondly, cheerful companionship about an invalid is more conducive to rapid improvement than one of invalids, with the constant reminder of the nearness of death. Lastly, the age of the patient as a psychological factor is important in considering the effect of the change to be made. It is true that "hope springs eternal in the human breast," but it springs more exuberantly in the young breast, and we can count more upon this universal element in human nature in the young than in the middle-aged and older. The adaptability of the young to change and new conditions is great, and with them we can venture on more radical changes than with the older, who are bound by long association to friends and places. Ours is a materially scientific age, and medicine feels the influence of the time and age, but there is a mental as well as a physical side to the human entity, and he is the wise physician who duly weighs in his considerations and decisions the influences of the spiritual side as well as that of the physical.

Dr. Griffith E. Abbott, Bryn Mawr, Pa., read a paper on

THE BASIS OF RATIONAL CLIMATO-THERAPY.

We should guard against ascribing qualities to climate as peculiarly characteristic, which are disturbances either incident to acclimatization or are the result of our short-sightedness, or the patient's carelessness.

Medical climate resolves itself into a microscopically pure air, equability of temperature, sufficient warmth and humidity, abundance of sunshine, protection from harmful air, air currents, and the presence of such arrangements and regulations as will enable the patient to lead a healthful life — a

climate in which much outdoor exercise can be taken.

In selecting a place for sojourn, we should consider the conditions and exigencies of the patient, and also his local relations. The patient not appreciating the mode and circumstances of life among the inhabitants of a place, can only enjoy the climate, and the local and social influences, such valued adjuncts, are lost.

DR. ISAAC HULL PLATT, of Lakewood, N. J., read a paper on

THE PINE BELT OF NEW JERSEY, A REGION OF SANDY SOIL AND PINE FORESTS.

It was my intention at this meeting of the association to present a paper in consideration of the subject of soil dryness and pine forests with reference to pulmonary diseases, but I have found that it requires an amount of research for which I have not yet had time, and I shall for the present content myself with briefly calling attention to a region where these conditions prevail And it is of special importance by reason of its nearness to our great Eastern cities.

New Jersey, though a small State, presents considerable diversity in its topographical and geological features. In the northern part it is traversed by the Kittatinny Mountains, a range of hills, part of the great Appalachian chain. The central portion is characterized by red sandstone with trap ledges, while the southern and eastern portions of the State consist of level country with a sandy soil and pine forests. Along the shore there are long stretches of shallow bays and tide marshes, and in the extreme southern portion many little rivers with meadows lying along their banks. But running through the interior of the State there is a strip of land about sixty miles in length, and from eight to twenty miles in breadth, reaching from a few miles south of Freehold in Monmouth county almost to Vineland in Cumberland county. This comprises the inland portion of the sandy tract, including the extreme southern portion of which I have spoken. This region has long enjoyed a local reputation for healthfulness, and some portions have been mainly settled by people who have gone there for that reason. Extensive pine forests are a prominent feature of this region. They have been in some places cut off or burned, and in some spots are replaced by oak and other deciduous trees. But there are enough left to make it prominently a pine region.

The importance of soil dryness as a climatic element in prophylaxis of phthisis is too well known to need rehearsal. According to the reports of the State Board of Health, which are carefully prepared, and are, I believe, as accurate as any statistics of the kind, the whole number of deaths in the townships of Howell, Jackson, Manchester, Southampton, Woodland, Shamong, Winslow, and Hammonton, during the six years from 1883 to 1888 inclusive, was 1057, or an average of 12.16 per thousand a year. The number of deaths from consumption was 141, or 1.6 per thousand a year. In the State of New Jersey, during the same period, the total mortality was 18.65 per thousand, and the mortality from consumption 2.53 per thousand. Or, throwing out towns of over 5000 inhabitants, the total mortality was 15.07 per thousand, and the mortality from consumption 2.12. The comparatively low mortality from consumption will be rendered more striking if attention is called to the nature of the population of the region. The inhabitants may nearly all be included in two classes, — the descendants of the original settlers, and those who have settled themselves in this region because of its supposed healthfulness.

At some future time I hope to be able to give something more definite in regard to the results of treatment in this region. I can only say at present that it is very exceptional for a patient with bronchial or pulmonary disease not to derive some benefit, greater or less, from the change, and in many cases the benefit has seemed remarkable.

DR. ALBERT L. GIHON read a paper on

OCEAN THERAPY.

A paper by DR. S. H. CHAPMAN, of New Haven, entitled

NOTES ON THE PRESENCE OF DIPHTHERIA AT HIGH ALTITUDES,

was read by title.

In August last, during an excursion to Franz-Josefshöhe, 9500 feet high, into the heart of the great glacial region called Gross-Glockner, in eastern Austrian Tyrol, my guide related circumstances of an epidemic occurring during the early spring of the preceding year in his native village of Heiliegenblut, which aroused my curiosity. On my return to the village of Heiliegenblut, which is the starting point of all excursions into that region of snow, I made inquiries of the factota of the village, of the hostess of the inn, who is the chief personage in all the Tyrolean villages, the postmaster, and telegraph operator. Their statements verified and amplified those made by my guide. Upon my return to Lienz I called upon the only physician of the town, who is also the military surgeon in charge of the government hospital for the district of Lienz. He gave me a description of his share in the epidemic. At the end of a week of the plague, as the peasants call it, notwithstanding the danger attending the journey, a messenger was despatched for a doctor, who, after a toilsome journey of two days, reached the village. The physician pronounced it diphtheria of virulent type. His treatment consisted of insufflation of sulphur and poultices on the neck. His treatment was so unsuccessful that the peasants had recourse to charms, prayers in the church night and day, and to the aid of an aged peasant, whose treatment saved more lives than the doctor's. It consisted of an ointment of sweet cream and powdered gunpowder rubbed in on the outside of the throat, and inside as well. The physician's statistics were sixty cases, forty-eight deaths. The disease was entirely unknown to the oldest inhabitant. The description of the disease was somewhat limited, namely, the crisis was reached in from two to three days; besides the swelling of the glands and inflammation of the throat, there was even severe hemorrhage from the nose preceding collapse. There was no attempt made to isolate cases. I have related this incident to the society because of the interest attached to the extent of the development of diphtheria at so high and isolated a spot.

It seems possible to draw the following conclusions: That the latent germ was stimulated to active development in the steaming, fermenting atmosphere of a stable; that its virulence was rather increased than diminished by the high altitude and by the rarity and low temperature of the air; that propagation from house to house was not hindered by the passage of the germ through a rarefied air of very low temperature; that the effect of the germ became less and less violent as time elapsed; that the history of this epidemic seemed to show that there took place a special culture of the specific microbe in defined quantity; that all the cases were attacked by the originally developed microbe, and that under the wearing action of it and atmospheric conditions its virulence became more and more attenuated, until it again passed into a harmless period of existence, or became secluded in localities unpropitious for further development.

NEW YORK ACADEMY OF MEDICINE.

Stated meeting, May 20, 1889.

Dr. W. Gilman Thompson read a paper on

THE THERAPEUTIC VALUE OF OXYGEN INHALATION, WITH EXHIBITION OF ANIMALS UNDER HIGH PRESSURE OF OXYGEN.

He said that he had been impressed by the fact that while some observers claimed the most brilliant therapeutical results from the use of this agent, others held that it was of but little, if any, practical value, and still others used it in such a vague way that no reliance could be placed upon the results obtained. As was well known, the ordinary pressure of the atmosphere was fifteen pounds to the square inch; of this amount three pounds was exerted by the oxygen and twelve pounds by the nitrogen. The first question that arose was, Does an increased pressure really cause more oxygen to be absorbed? Under any circumstances the hæmoglobin of the blood could take up but 2½ per cent. more of oxygen, and it was also a fact that it could not enter the plasma to any extent.

In most of the older text-books it was stated that animals could not live in pure oxygen, the system being burned up, as it were, by the increased tissue changes excited by it. This idea, however, was an entire mistake, as was conclusively demonstrated by Dr. Andrew H. Smith in the series of experiments made by him in 1869 and 1870. Having referred to some of the symptoms produced in the human subject by the inhalation of oxygen, he said that very little additional oxygen could be made to enter the system by any amount of pressure short of that which would result in injurious effects.

He then exhibited the apparatus which he had had constructed for the purpose of exposing animals to high pressures of oxygen. It consisted of a strong iron drum, or chamber, with glass-covered openings at each end, in which the animal to be experimented upon was to be placed; and to this oxygen was supplied at any degree of pressure desired, from a cylinder containing the gas at a pressure of 225 pounds to the square inch. Two animals, a monkey and a pigeon, which had been subjected for one hour to a pressure of 30 pounds to the square inch, in oxygen, in addition to the ordinary pressure of the atmosphere, 15 pounds, were taken from the chamber in an apparently perfectly normal condition.

Dr. Thompson next proceeded to make a detailed report of a number of experiments he had made upon animals which were in a normal condition at the time the experiments were commenced, the animals being dogs, cats, pigs, monkeys, guinea-pigs, pigeons, and alligators. It was found that all the animals could exist comfortably in the oxygen until a pressure exceeding three atmospheres was reached. The higher the order of the animal experimented upon the more quickly it became affected. As a rule, a decided fall of temperature, often amounting to from four to six degrees Fahr., was observed; and only in cold-blooded animals was there any rise of temperature. This marked decrease in temperature he did not believe was to be attributed at all to the effects of the oxygen, but to the profound disturbances caused in the system by the high pressure employed. If, as was claimed by the older writers, a greatly increased tissue metamorphosis was caused by oxygen, this would unquestionably be accompanied by an increase, and not a diminution, of the body temperature. In a paper read before the Royal Academy of Madrid, Valenzuela reported similar results. In animals subjected to oxygen in a pneumatic chamber under increased pressure he found that the temperature was reduced several degrees, and rabbits in which septicæmia had been artificially produced had the temperature reduced to normal.

In such of the animals as died as a result of subjection to high pressure of oxygen, or were killed after removal from such exposure to high pressure, Dr. Thompson found pulmonary engorgement and dilatation of the right heart. The convulsions which usually resulted when the pressure was carried to a high point were, as a rule, quickly controlled by blowing off five pounds of pressure. He also tried the experiment of subjecting animals on alternate days to high pressure of oxygen and to compressed air, the series of observations being maintained for a considerable period. The cause of the convulsions produced by exposure to high pressure of oxygen, he said, was as yet undecided, but he was inclined to attribute it to the difference in the diffusion of oxygen and carbon dioxide under different degrees of pressure.

A second series of experiments was performed upon animals in which abnormal respiration had been induced. Dyspnœa might be classified as being due.

(1.) To abnormal conditions of the air.
(2.) To abnormal conditions of the blood.
(3.) To obstructed circulation.
(4.) To diminished surface for aeration.
(5.) To neurotic influences.

In a cat in which dyspnœa was produced by cutting both vagi instant relief was afforded by exposing the animal to oxygen; while, on the other hand, the dyspnœa was increased by compressed air.

In the second experiment a canula was introduced into the pleura of a dog. In the third pulmonary congestion was caused in a cat by injecting

a solution of nitrate of silver into the lung-tissue, and the dyspnœa resulting therefrom was greatly relieved by oxygen. In other experiments the lung was compressed by injecting considerable quantities of water into the pleura, and in still others the animals were bled to the extent of many ounces. The results of these experiments, he said, went to show that oxygen does aid in a moderate degree certain types of dyspnœa.

In considering the therapeutic value of oxygen it was to be borne in mind that it was a physical impossibility to take oxygen into the blood. This agent had been employed, first, as curative in certain general diseases, more particularly of the blood and circulation, and, second, as a palliative in dyspnœa due to various conditions. Of late its use had increased to such an extent that two or three hundred thousand gallons of it were now consumed annually in New York city alone. Among the affections, beside dyspnœa, in which it was claimed that it had proved of benefit were anæmia, chlorosis, croup, chronic gastric catarrh, migraine, cholera, and opium narcosis. It was used more generally in this country and on the continent of Europe than in England, and in Paris a supply was kept on hand at the stations along the Seine for use in resuscitating persons rescued from the river, and also at some of the police and fire stations.

In anæmia, chlorosis, etc., Dr. Thompson said he could see but little advantage over good fresh air in giving diluted inhalations of oxygen two or three times a day, as was the usual practice in such affections. It did not seem rational to him to expect that sufficient oxygen could enter the system under these circumstances to produce anything but a temporary effect at the best. In cases of blood-poisoning, again, he had failed to see any benefit derived from oxygen. In certain subjective cases of dyspnœa it no doubt gave relief, but in a case of poisoning by illuminating gas which he had seen at the Presbyterian Hospital it was kept up for nearly three days without producing any effect either on the rate of breathing or on the cyanosis present. In cardiac diseases his experience with oxygen had not been encouraging, and he referred particularly to a case of malignant endocarditis in which it proved of no avail in relieving the dyspnœa. In certain cases of asthma and of anæmic dyspnœa, however, it gave decided relief, and in such he believed it was an invaluable therapeutic agent; though not, of course, curative.

DISCUSSION.

DR. J. WEST ROOSEVELT spoke of the relation of the amount of oxygen inhaled to that absorbed, and said that while the amount which entered the plasma or the hæmoglobin of the blood was comparatively small, he believed it was sufficient to cause appreciable results in many instances. As to the therapeutic value of oxygen, in the neurotic form of dyspsnœa we had a condition in which the mere act of inhalation and the engaging of the attention of the patient would often have a beneficial effect. In anæmia he had met with fairly good results with oxygen, though the patients improved less rapidly than under the use of iron. If in any case the hæmoglobin was not saturated, an improvement showed that more oxygen was carried than under ordinary circumstances. On the whole, oxygen had proved of considerable value in his experience, and in cases of diminished surface for aeration he had seen cyanosis decidedly improved under its use.

DR. GEORGE L. PEABODY said that so many circumstances were involved in estimating the value of an agent like oxygen that it was difficult to arrive at positive conclusions respecting it. Thus, when it was not the only therapeutic agent employed, it was impossible to say just how much benefit was derived from it; and this difficulty was further increased in diseases which naturally tend to recovery. The question of the utility of oxygen he believed was still undecided. When the idea of its administration first occupied the profession it was the practice to give internally chemical substances, like chlorate of potassium, for instance, which were known to be rich in oxygen. It was far from certain, however, whether they yielded up their oxygen on entering the body; and even if this were so it seemed probable that the resulting compounds might have a more or less caustic effect upon the tissues. This was apparently the case with osmic acid.

Later it had become the practice to give oxygen by inhalation. Under such circumstances its absorption depended probably on the amount of hæmoglobin in the blood at the time the oxygen was administered; but in any event the amount absorbed was unquestionably small. There was good reason to doubt the alleged efficiency of this agent, and personally he believed that, as a rule, quite as much relief could be obtained from ordinary fresh air. It might be tried, however, in maladies attended with dyspnœa, in which the blood is unchanged, such as pneumonia, emphysema, croup, and asphyxia from toxic gases; although, as Dr. Thompson had correctly stated, in poisoning from illuminating gas it had failed to give relief. There was no justification, he thought, for the extensive use of oxygen in general diseases, such as anæmia, chlorosis, lithæmia, etc. Although the pulmonary gymnastics of the inhalations might have a beneficial effect in certain instances, there were other remedies which could be employed with much greater advantage. That the use of oxygen hastened recovery in such cases he did not believe, and the recognized facts of physiology were certainly at variance with any such conclusion.

DR. BEVERLY ROBINSON said that he differed entirely from Dr. Peabody, and that his clinical experience afforded the most conclusive proof of the immediate and marked relief resulting in many conditions from the use of pure oxygen. In anæmia he had found that those cases were most improved in which oxygen was used in connection with iron. The purity of the gas was a point of the utmost importance, and he said that one make of gas which he had formerly employed gave such poor results that he ceased to use it. There was a gas now manufactured in New York which was said to contain a certain proportion of nitrogen monoxide, from which he had obtained very satisfactory results; and it was worthy of note that Brown-Séquard had expressed the opinion that nitrogen was of great service in preventing the irritating and intensely exciting effects of oxygen alone.

In albuminuria connected with atrophic nephritis he had found the general nutrition of the patient notably improved under the use of oxygen; the digestive and assimilative powers being greatly assisted by it. Even in phthisis, while it did not have a curative effect, it might prove beneficial. In the first place, the inhalations caused the patient to thoroughly expand his lungs; secondly, oxygen was itself an antiseptic, and therefore indicated; and, thirdly, it had the effect of improving the general nutrition. As had been well said, oxygen was really prescribed every time that a patient was sent to the mountains, to Southern California, to the plains, or on a sea voyage. But there were many cases in which it was impossible to send patients away, and he believed it was possible to stimulate the hæmoglobin in the blood, and thus to enable the patient who remained at home to carry more oxygen. In the use of oxygen he did not think we should be guided so much by experimental researches as by practical clinical experience. Without considering the curative effects of the remedy, there were certainly many cases where the last hours of patients could be rendered much more comfortable by resorting to its use.

Dr. Walter Mendelson said that he felt compelled to agree with Dr. Peabody from what he had observed of the effects of oxygen. In anæmia it was true that he had seen some quite marked results under its use; but he did not believe that the benefit was in reality due to this agent. He cited the case of an old man who inhaled ten gallons of oxygen a day, and became greatly improved. This improvement, however, he was convinced was due to the systematic expansion of the lungs and to the moral effect of the knowledge that something out of the common was being done for him. In cases of dyspnœa from various causes he had seen more or less relief afforded by oxygen; yet all the patients died. Still, as Dr. Robinson had said, it was possible that their last moments were rendered more comfortable by the inhalations.

Dr. Mary Putnam Jacobi said that the amount of oxygen which the hæmoglobin carries varied under different circumstances. In asphyxia of various kinds the physiological capacity of the blood remained the same, and therefore the indication was to administer oxygen. The correctness of this had also been shown by clinical experience. In anæmia, and especially chloro-anæmia, on the other hand, the hæmoglobin was diminished. The condition was precisely the reverse from that met with in asphyxia, and we could not cause a much greater amount of oxygen to be absorbed.

Dr. Andrew H. Smith said he was gratified to find that the work which he did twenty years ago for the most part still remained good. At that time he had demonstrated that animals could live perfectly well for four days in pure oxygen; care being taken to remove the effete products of respiration. It was his opinion that under ordinary conditions the blood is not fully saturated with oxygen, and that the point of saturation corresponds with the physical demand. This allowed a pretty wide margin, and it was perhaps within this margin that a considerable amount of oxygen could be absorbed by the blood. Thus, the demand for oxygen was much greater in athletes engaged in violent exercise than in individuals making but little physical exertion. Therapeutically he had seen the greatest benefit derived from oxygen in catarrhal conditions of the air-passages, such as was met with in suffocative bronchitis. In such cases he was at a loss how to explain the relief afforded by the oxygen, unless it was a fact that under these conditions the blood did not take up as much oxygen as the system required. When pneumonia was present so many conditions were brought into play that the matter was much more complex and the relief afforded by oxygen very uncertain. Dr. Smith also said he had used oxygen with satisfactory results in opium poisoning.

Dr. Thompson, in closing the discussion, said that convulsions were produced in the animals experimented upon by the rapid increase of the pressure, and that such convulsions were quickly relieved by the rapid withdrawal of a portion of the pressure. He could not agree with Dr. Smith in his opinion regarding the saturation of the blood with oxygen, since he thought there could be no question that even under ordinary conditions the hæmoglobin was practically saturated with oxygen. In reply to Dr. Roosevelt he said that many individuals suffered from dyspnœa whose blood contained more oxygen than that of those with anæmia or suffering from hæmorrhages. Dr. Robinson was certainly mistaken in attributing any irritating effects to oxygen. Pure oxygen had no irritating effects whatever, as had been repeatedly demonstrated. It produced no burning up of the tissues, as had been formerly supposed, and he could see no advantage over ordinary air in the nitrogen monoxide referred to.

During the evening a cat and a dog were successively subjected to progressively increasing pressures of oxygen in the pneumatic chamber. When the pressure reached eighty pounds to the square inch the cat was seized with a convulsion, and the dog had a convulsion when the pressure reached a little above forty-five pounds. That this effect was not due to carbon dioxide was shown by the lime-water test. Both animals recovered after they were restored to the air.

Recent Literature.

Pathological Report, 1887-1888, of The City of London Hospital for Diseases of the Chest, Victoria Park, E. By Sidney Martin, M.D. (Lond.), Assistant Physician to the Hospital, Late Pathologist and Medical Registrar.

This report includes an analysis which, from a pathological point of view, is pretty complete, of forty-nine fatal cases of phthisis and tuberculosis; sixteen of cardiac disease; and a few of empyema, bronchitis, etc. In many respects the clinical analysis is also good; but we note that the sputum seems to have been examined for bacilli in only seventeen of the forty-nine tubercular cases, and in four of these with negative result; in only two of the four, however, was the examination repeated. The immediate cause of death in two cases was hæmoptysis. The intestines were ulcerated in twenty out of thirty-eight cases, and in thirteen of these there was diarrhœa; in eight, well-marked constipation; in one, regular bowels; it should be

added that in the majority of the constipated cases no opiates, to the use of which the constipation could be attributed, were administered, and that in the others the amount of opium was small. It is greatly to be desired that all institutions for the care of the sick should be provided with pathologists as devoted and a management as liberal as the Victoria Park Hospital enjoys. It would not take long to accumulate a mass of facts of the greatest value and interest.

Diabetes, its Cause and Permanent Cure, from the Standpoint of Experience and Scientific Investigation. By EMIL SCHNEE, M.D., Consulting Physician at Carlsbad, and Physician to the Imperial and Royal Consulate of Austria and Hungary for the Riviera at Monaco. Translated from the German by R. L. TAFEL, A.M., Ph.D. English edition, revised and enlarged by the Author. Philadelphia: P. Blakiston, Son & Co. 1889.

The author claims to have made, in 1881, the important discovery that the ætiological element of diabetes is syphilis contracted by some ancestor of the patient. He also maintains that diabetes is curable under his treatment, which, however, so far as we can discover, differs in no essential respect from that commonly employed in this disease, except in the internal administration of corrosive sublimate albuminate and of chromate of potassium. He reports twelve cases of cure which had lasted for at least seven years each. While containing some useful information concerning the views of eminent authorities on the nature and treatment of diabetes, this work is written in an *ad captandum* style, and in a spirit of self-glorification, which seriously detract from its value.

Examination of Water for Sanitary and Technical Purposes. By HENRY LEFFMAN, M.D., and WM. BEAM, M.A. Philadelphia: P. Blakiston, Son & Co. 1889. viii, 106. 12mo.

The authors, in compiling this manual, have selected the more modern and practical chemical methods which have been proposed for the examination of waters for the purposes indicated by the title. These they have described clearly and concisely. They make but brief mention, however, of the bacteriological examination, considering it as beyond the scope of their work. The advice given in regard to the proper interpretation of the results obtained in the examination are very practical, and the little work can therefore prove a useful addition to the literature of its subject.

Parreidt's Compendium of Dentistry. Translated by LOUIS OTTOFY, D.D.S. With notes and additions by G. V. BLACK, M.D., D.D.S. Published by W. T. Keener. Chicago. 1889.

The work is intended for a text-book in the dental schools. Its accuracy and conciseness are to be commended. Drs. Ottofy and Black, both distinguished American dentists, have added much to the value of the original work in adapting it to the needs of the dental student in this country.

The work is divided into twelve chapters. The first is devoted to a consideration of the anatomy and physiology of the teeth. There follows a chapter on anomalies and seven on diseases of the teeth and jaws. These latter are the most important in the book and contain much valuable matter by Dr. Black in addition to the original text. The author accepts the view of Miller that decay is the result of fermentation. In treating of chronic alveolar abscess, it is quite refreshing to hear the statement made that a certain proportion of the cases are incurable. I rarely meet with any dentist who is always successful in these trying cases. Pyorrhœa alveolaris is not considered an infectious disease as Wetzel has claimed, nor does the writer believe it to be a constant symptom of diabetes. Dr. Black believes it to be a specific disease of the peridental membrane, and that the condition of the alveolar wall is secondary.

The remaining chapters are devoted to filling, extraction, and the construction of artifici l plates. The chapter on filling is the least valuable in the work, and is too limited to be reliable.

Manuel Pratique de la Garde-Malade et de l'Infirmière. Tome V. Hygiène, par Sollier, Interne des Hôpitaux, professeur à l'École municipale d'infirmières et d'infirmiers de Bicêtre. Paris: Aux Bureaux du Progrès Médical. 1888.

This little volume upon the subject of general hygiene, or preventive medicine, is the fifth of a series of handbooks adapted to the wants of hospital nurses of both sexes, and is one of the publications of *Progrès Medical*. It is written in an easy, simple, and somewhat elementary style, and treats concisely of those subjects which come within the domain of hygiene. Two different classes of conditions affect the health of mankind; those which act from without, and those which are inherent in the individual (such as sex, age, race, heredity, constitutional resistance, etc.) The author confines himself to the former.

The principal topics treated in its twelve chapters are air, light, heat, endemic and epidemic diseases, the house and its environment, ventilation, heating, clothing, care of the body, bathing, food, meat, vegetables, condiments, and beverages.

Eighth Registration Report of New Hampshire. 1887.

The registration of vital statistics in New Hampshire is under the supervision of the secretary of the State Board of Health. The report of 1887, just published, shows an improvement in the line of public registration over previous years.

The number of births registered in 1887 was 6910; of marriages 3495; and the deaths were 6479. These would indicate, when estimated upon the population of 1880 (346,991), a birth-rate of 19.91 per 1000; a marriage-rate of 10.07; and a death-rate of 18.67. The excess of the birth-rate over the death-rate, or natural increase, was therefore 1.24 per 1000.

The rates for Massachusetts for the same year were as follows: birth-rate 26.45; marriage-rate 9.72; death-rate 20.28; and excess of birth-rate over death-rate 6.17 per 1000, upon an estimated population of 2,010,388.

The percentages of deaths at different ages were as follows, as compared with Massachusetts for the same year: —

	Under 1 year.	Under 5 years.	20 to 30 years.	All other ages.
New Hampshire,	14.62	22.14	7.21	70.64
Massachusetts,	20.89	32.26	9.51	58.23

The percentage of deaths from different causes by classes in the two States was as follows: —

	Zymotic.	Constitutional.	Local.	Developmental.	Violent.	Unspecified.
N. H.,	17.9	20.4	45.7	12.1	3.6	1.3
Mass.,	19.5	22.3	42.2	10.6	4.2	1.2

By counties, the zymotic diseases varied from 9.7 per cent. of the total number in Cheshire to 33.7 per cent. in Coös.

The mortality from the most prominent causes of death was as follows: Consumption, 766 deaths; heart disease, 575; pneumonia, 556; apoplexy and paralysis, 463; old age, 449; cholera infantum, 336; cancer, 218; violence, 182; diphtheria, 177; typhoid fever, 134; brain diseases, 121; bronchitis, 114; diarrhœa and dysentery, 107.

This order of fatality differed but little from that of Massachusetts in 1887. In the latter the number of deaths from pneumonia was greater than those from heart disease; and those from cholera infantum were more than those from old age. Cancer also stood higher in the list in New Hampshire than in Massachusetts.

It is to be hoped that all of the States of the Union will soon adopt efficient systems of registration, that the true condition of the people may be known from year to year, so far as the natural movements of the population are concerned.

Manuel Pratique de la Garde-Malade et de l'Infirmière. Publié par le Dr. Bourneville. Tome I. Anatomie et Physiologie. 4e edition revue et augmentée. Paris: Aux Bureaux du Progrès Medical. 1889.

In spite of certain useful practical suggestions which this little primer for nurses contains, it does not strike us as particularly adapted to the object in view. Although the anatomical part is meant to be sketchy, it touches on a number of points which are really details, and is not always accurate. We doubt whether illustrations of dissections are of any practical use in a book of this kind. The physiology does not please us any better.

Elements of Histology. By E. KLEIN, M.D., F.R.S., etc. Philadelphia: Lea Brothers & Co. New and enlarged edition, with 194 engravings.

Dr. Klein's little work is so well known by this time on both sides of the water that it requires no detailed notice. The present edition shows some changes to bring it up with the times. Dr. Klein has accepted Rollet's views on the structure of muscular fibre, and gives a short sketch of the results of recent work on the nucleus. The text is concise and the illustrations very fine.

— Among the new medical graduates who are beginning to get a foothold in practice is the Archduke Charles Theodore of Austria, who recently commenced to practise as a duly qualified medical man near Méran. A short time ago he treated successfully a patient of seventy-four years of age under circumstances which so strongly impressed the popular imagination that the archducal doctor was fêted by his enthusiastic neighbors. The Archduchess, who has for some time past assisted her husband in performing the more serious of his operations, is said to have begun to "quiz" in preparation for examinations which will place her also on the list of qualified doctors.

THE BOSTON
Medical and Surgical Journal.
THURSDAY, JULY 25, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of The Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money order, draft, or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE UNICITY OF BRIGHT'S DISEASE.

TILL JOHNSON wrote in 1846, "On the Minute Anatomy and Physiology of Bright's Disease," no histological interpretation had been attempted of the lesions described by Bright nearly twenty years previously. Johnson concluded from numerous careful observations that fatty degeneration of the epithelia of the kidneys is the principle and essence of Bright's disease; the exudation of blood and serum in the urine is the consequence of the blood pressure augmented by reason of obstruction of the tubuli. Johnson in his first memoir states the view, since then generally adopted by histologists and clinicians, that the divers aspects described by Bright cannot be regarded as only different stages of one and the same disease. The small granular kidney has but little similarity to the large, white, soft kidney, and if the name of Bright's disease ought to be reserved for that renal degeneration which begins and progresses by fatty metamorphosis, the white kidney ought to be separated from the atrophied kidney.

Rayer, in France, in ranging his six forms under the common name of albuminous nephritis, although he nowhere says expressly that they may undergo transformation the one into the other, seems to admit that these forms are successive phases of one and the same process.

In Germany the microscope in the hands of Reinhardt and of Frerichs confirmed the unicist conception of Bright's disease. Reinhardt attributes the states described by Bright to an inflammatory process which he calls diffuse inflammation. But he thinks that, according to the causes which have produced it, according to the individuals in whom it has developed, this inflammation may follow a different course. He regards the varieties indicated by Bright as the diverse consequences of this diffuse nephritis. Like every inflammatory process, the renal inflammation may present itself to the

observer at different periods of the stages of congestion, of exudation with fatty degeneration of the epithelia, of connective tissue proliferation with ultimate retraction of the tissue of new formation.

Frerichs in 1851 arrived at the same conclusions. The alterations, he thinks, succeed each other in the following order: in the first stage there is hyperæmia with exudation into the renal parenchyma; in the second stage the exudation undergoes varied metamorphoses; which end in a third stage, in a process of regression and in atrophy of the glandular substance.

In England the tendency to dualism became more and more marked after the publication of Johnson's researches. Samuel Wilks advanced the view that the term "Bright's disease" covers at least two diseases absolutely distinct. He criticised Frerichs' propositions. "If," he said, "the small granular and atrophied kidney is the last stage of a uniform process, of a succession of inflammatory congestions, of exudations and subsequent regressions, with ultimate retraction, how is it that we meet with so few instances of intermediate pathological states? Why has not a single case been mentioned where the symptoms which characterize the large white kidney have gradually undergone transformation, to end in those of the small, granular, contracted kidney? Why is there not a single case on record of the small contracted kidney where acute symptoms preceded the chronic evolution of the disease?"

Wilks constituted two principal varieties, altogether distinct, of renal lesions: the large white kidney, and the small contracted kidney. The causes, symptoms, and course of these two varieties are different. Wilks was one of the first to call attention to the frequent association of the renal lesion with alterations of all the tissues, and, in particular, of the heart and arteries.

Dickinson placed himself on the dualist side, and divided Bright's disease into two great varieties: 1, *tubular nephritis*, acute or chronic, which is primitively a catarrhal inflammation of the canaliculi, ending in the large, white, soft, or mottled kidney, and, where life is sufficiently prolonged, in a certain degree of atrophy; and, 2, *intertubular nephritis*, in which there is an exudation between the tubuli which involves the secreting tubuli and the glomeruli in a gradual destruction, the process ending finally in the small contracted kidney.

Grainger Stewart, in 1868, adopted a similar division, and insisted that it was more logical to say Bright's diseases than Bright's disease. Jaccoud defends the plurality of forms in his *Pathologie Interne*, and so do Bartels, Charcot, and Lancereaux in their special treatises. In 1872 Gall and Sutton furnished still other arguments for plurality in the notions which they formulated respecting *arterio-capillary fibrosis* and its relations with the contracted kidney. Lecorché, in his classical work, *Maladies des Reins*, published in 1875, makes of pathological anatomy the basis of his division. He admits two great varieties of renal inflammations, according as the lesions affect the canaliculi or the intertubular connective tissue: the first variety constitutes the parenchymatous nephrites, the second, the interstitial nephrites. He also describes mixed forms, and insists on the frequent combination of interstitial nephritis with grave or "profound" parenchymatous nephritis; amyloid degeneration is described in a separate chapter. Lecorché would reserve the name Bright's disease for profound parenchymatous nephritis, which presents four periods; a period of hyperæmia, a period of hyperplasia, a regressive or fatty period, and a period of atrophy or collapsus.

It is significant of the provisional character of the theories hitherto prevalent respecting the renal diseases, that Lecorché, in the recent admirable treatise, "On Albuminuria and Bright's Disease," which he has published in conjunction with Charles Talamon (a work from which we have borrowed in the foregoing exposition), has abandoned the dualist view which he formerly entertained, and has declared himself a unicist. The considerations which have led to this change are very clearly set forth in the second part of his work; they are considerations derived from the more intimate knowledge which the studies of the past twenty years have given of the morbid anatomy and histology and clinical history of Bright's disease.

We intend in another number to present the principal arguments which these writers have advanced in support of the unicist view.

SIR ANDREW CLARK ON HOSPITALS.

AT a recent meeting in London, held at the Mansion House, in behalf of the Hospital Sunday Fund, Sir Andrew Clark, President of the College of Physicians, was the principal speaker. He set forth in a very plain, forcible way the benefits which hospitals confer upon large, crowded communities, and the corresponding claims which they have upon all classes of such communities. He gave an admirable summary of the reasons why the whole population of any great city is equally interested in the support of its great hospitals. That they are a blessing to the poor man is not likely to be overlooked, but that they prevent the spread of epidemic diseases; hinder the outbreak of pestilence; and serve as the true nurseries of the medi-

cal skill and intelligent care which every man and woman is likely to have to call upon some day, are facts which the general public and the well-to-do need to have kept before their eyes. But there is still another service of a politico-social character which hospitals render in large centres of population, which is surely very much overlooked, and which we are glad to see alluded to by Sir Andrew in these words: "I do not know that there is anything so trying to the faith of mankind or to the order of their lives as to see those whom they love get sick and grow worse and unassisted. Now, in the great centres of population, such as we know a good deal about in the east of London, it is an enormous advantage to keep down those terrible revolutionary feelings which are apt to arise in the breasts of men when they look upon those whom they love crowded together in poor miserable hovels, sick and suffering, with no one, as they think, to relieve or care for them. It seems to me that in this there is a service which hospitals do render to the community and which the community in these days forgets."

The income of the great London hospitals has been diminishing of late years, while the demands made upon them are continually increasing. The agricultural distress has diminished the proprietary income of the old hospitals, and, in so far as they are dependent upon voluntary contributions, they suffer from what this address terms a diminution in the strength and virtue of giving. Sir Andrew Clark believes, moreover, that the great general hospitals are robbed of some of the support which they ought to receive by the foundation and maintenance of improper hospitals which divert funds in directions in which they ought not to be employed.

He pays his respects to special hospitals in the following sentences: —

"A doctor who cannot get on in the ordinary way takes to studying the great toe, and he discovers something about it never known before. In the course of his studies he ascertains that the diseases of the organ are not only supremely important in themselves, but that they have the most intimate relation to all the other serious diseases of the body. He also invents a wonderful instrument whereby he can look into the great toe and see what is threatening, and prevent all those terrible things which happen in the organ and affect the whole system. He goes to his friends, shows them his instrument and tells them of his discoveries. They then club together and establish a Hospital for the Treatment of the Diseases of the Great Toe. They soon get patients who are convinced of the vast importance of the diseases of the great toe. Marvellous cures are effected and all sorts of frightful diseases are prevented. They have an annual meeting. They have a chairman who sets forth bashfully in the presence of the great physician the diseases of the great toe, the wonderful things that have been done, the great service which has been rendered by the hospital, the terrible prejudice it has had to encounter, and the determination that this great institution shall be liberally supported, notwithstanding the prejudices of the medical profession and of those who herd with them."

There has been a disposition to curtail or abolish the out-patient departments in connection with some of the London hospitals, but Sir Andrew, who has probably had as large an experience with them as any one in London, comes vigorously to their defence. Where else, he asks, can the doctor come face to face with the early aspects of disease, where else with those first small indications of disease which tell of its near approach and which are still within the power of art to avert? The doing away with these departments of the great London hospitals would, he thinks, inflict a cruel, irreparable wound on practical medicine in his country.

The opinion that special hospitals have been overdone in London seems to be part of the best medical sentiment, and there is nothing in the remarks of Sir James Paget, Sir Henry Acland, and others at a recent meeting in Oxford, held in behalf of the Eye Hospital of that place, which controverts this opinion. A tendency to the same error has for some years been manifested in our own large cities.

MEDICAL NOTES.

— At the Johnstown flood, six physicians were drowned and twenty-one lost all they had.

— Mrs. Jane C. Stormont, widow of the late Dr. D. W. Stormont, of Topeka, has given 10,000 dollars to the Kansas Medical Society, for the purchase of a library.

— At its recent commencement, the Medical School at Burlington, Vt., gave diplomas to fifty-six graduates.

— Vermont is about to build a new State Insane Hospital at Waterbury. Five hundred acres of land have been purchased, of which thirty acres, in the vicinity of the Central Vermont R.R. Station, are to be used as a building site. The complete plans contemplate a three-story brick building, having a frontage of 900 feet. There will be a central administration building. The main building will consist of two wards, one for men and one for women, connected on each side by a corridor one story high. In each wing will be three two-

story circular wards for the chronic insane. Each ward consists of a day room on the first floor, and has a dormitory for 25 patients. There will be a general hospital ward, three stories high and 150 by 36 feet in size, with a capacity for 75 patients.

— Dr. Donald McLean, Professor of Surgery, and Dr. G. B. Frothingham, Professor of Ophthalmology, at Ann Arbor, have resigned; and Dr. C. B. Nancrede, of Philadelphia, and Dr. Fleming Carrow of Bay City, Michigan, have been appointed.

NEW YORK.

— In consequence of the finding of three dead bodies in the large Croton reservoir in Central Park within three months, the board of health has called the attention of the Park Commissioners and the Commissioners of Public Works to the matter, with a view to the prevention of such suicides in the future. It is suggested that the reservoir should be surrounded with so high a fence as to render it extremely difficult to gain access to the water, and that the Park Commissioners increase the police force on duty in the vicinity of the reservoir.

— The board of health has followed up the report of its pathologists on the contagiousness of tuberculous diseases with the publication of a series of rules to be observed for the prevention of consumption. The first directs that the sputa of suspected consumptives should be received in earthen or glass dishes containing a solution of bichloride of mercury, 1 to 1000. The other rules are as follows: —

2. Do not sleep in a room occupied by a person suspected of having consumption. The living rooms of a consumptive patient should have as little furniture as practicable. Hangings should be completely avoided. The use of carpets, rugs, etc., ought always to be avoided.

3. Do not fail to wash thoroughly the eating utensils of a person suspected of having consumption as soon after eating as possible, using boiling water for the purpose.

4. Do not mingle the unwashed clothing of consumptive patients with similar clothing of other persons.

5. Do not fail to catch the bowel discharges of consumptive patients with diarrhœa in a vessel containing corrosive sublimate one part, water one thousand parts.

6. Do not fail to consult the family physician regarding the social relations of persons suffering from suspected consumption.

7. Do not permit mothers suspected of having consumption to nurse their offspring.

8. Household pets (animals or birds) are quite susceptible to tuberculosis: therefore do not expose them to persons affected with consumption: lso do not keep, but destroy at once all household pets suspected of having consumption, otherwise they may give it to human beings.

9. Do not fail to thoroughly cleanse the floors, walls, and ceilings of the living and sleeping rooms of persons suffering from consumption at least once in two weeks.

Ten thousand copies of these rules are to be printed for distribution.

Miscellany.

PRESIDENTIAL ADDRESS AT THE ANNUAL MEETING OF THE OHIO STATE MEDICAL SOCIETY.

In his address, as president, at the last annual meeting of the Ohio State Medical Society, Dr. P. S. Connor, of Cincinnati, said:

As is the appendix to the intestinal tract, a useless survival of a once important organ, so is the presidential address to the annual proceedings of the State Medical Society. In the days when books and journals were few, communication slow, professional work physically harder than at present, there was, I doubt not, good reason for requiring of the recipient of high honor an abstract of the year's progress, suggestions of work that might and should be done, or report of diseases and injuries carefully investigated and successfully treated. Now that to each one of us what appeared in print but a short time ago in San Francisco, Boston, Vienna, or St. Petersburg is familiar talk it may be well asked of the inaugural address, *Cui bono.* Hardly yours; surely not his to whom the months of prospect of its preparation are as the fly in the ointment of the apothecary. But custom is imperious and we are all its slaves. Like my predecessors I obey its mandates.

The year just closed, unmarked by any epoch-making discovery, has been one of busy work at home and abroad. In our own country laboratory study has been carried on as never before, and vivisections have thrown light on some obscure conditions. The work done at the congress at Washington in September last on the subjects of intestinal obstruction and cerebral surgery was of the greatest imaginable importance.

The State society, to command respect and be effective, must have a large membership. Out of the four thousand doctors in the State who bear no creed or limiting designation, only five hundred and sixteen appear on the roll of members published in the last year's *Transactions.* Contrast this to the one thousand seven hundred members of the Massachusetts State Medical Society out of about two thousand physicians. Nine counties in our State are unrepresented, and many others have but one, two, or three members. One-third of the members come from six counties. He advised the adoption of measures to bring in a larger membership, and thought it was wise to so amend the law that every regular physician, member of a county medical society, becomes through this a member of the State society.

In years past much of the time of the society had been devoted to "the regulation of the practice of medicine." He thought that the making of the

physicians of Ohio better diagnosticians and more successful attendants on the sick and the injured and the prevention of illy prepared men from entering upon the study of medicine should be sought for, but beyond this he had grave doubts as to the wisdom of interference. Public opinion is taking a turn all over the country in favor of legal restriction of the practice of medicine, and this would have the desired effect. Certainly it is not wise for medical men to be constantly decrying practitioners of medicine. The people of Ohio have to-day as good physicians as they ask for or are in fact entitled to. When they demand better and support better, then and not till then will they receive better. More medicine and less medical politics is, as I look at it, the want of the times in America.

He urged upon the society more work in the line of collective investigation of disease, and cited the good work done in this line by the State society of Texas. He recommended that the papers read before this society be short, clear statements of what the writers have themselves observed, studied, and done, leaving to the hearers, as disposed, investigation into the literature of the subject, and comparison of theories and conflicting opinions. "Never mind the items; give us the total."

He considered the social features of such a meeting by no means the least. If not a paper was read or a resolution discussed, he thought the gathering of the clan once a year well worth the trouble and expense. Such a tonic and such an alterative clear the brain and strengthen the heart. He referred in touching words to the death of Dr. D. Haldermann, of Columbus, first vice-president, who had earnestly, honestly, faithfully, and ably finished his life-work at fifty-seven.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 13, 1889.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3515, under five years 2.39; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1335, consumption 269, acute lung diseases 137, diarrhœal diseases 1125, diphtheria and croup 74, typhoid fever 29, measles 28, scarlet fever 28, whooping-cough 23, malarial fever 13, cerebro-spinal meningitis 11, erysipelas 4. From measles, Cincinnati 11, Philadelphia 6, New York 4, Chicago 3, New Orleans 2, Boston, Charleston, and Haverhill 1 each. From scarlet fever, New York 10, Philadelphia 8, Chicago 5, Washington 3, Baltimore and Lowell 1 each. From whooping cough, New York 12, Philadelphia 6, Boston 3, Washington and Lawrence 1 each. From malarial fever, New Orleans 7, New York and Baltimore 2 each, Philadelphia and Charleston 1 each. From cerebro-spinal meningitis, Chicago 4, New York 3, Washington 2, Philadelphia and Quincy 1 each. From erysipelas, New York 3, Boston 1.

In the 28 greater towns of England and Wales, with an estimated population of 9 555,406, for the week ending July 6th the death-rate was 17.7. Deaths reported 3249; infants under one year 1026. Diarrhœa 377, measles 97, whooping-cough 81, diphtheria 58, scarlet fever 55 fever 32.

The death-rates ranged from 11.2 in Nottingham to 29.2 in Newcastle-on-Tyne; Birmingham 14.3; Bradford 19.1; Hull 20.1; Leeds 26.9; Leicester 20.5; Liverpool 17.8; London 16.2; Manchester 25.3; Portsmouth 20.0; Sheffield 18.0; Sunderland 21.0.

In Edinburgh 17.4; Glasgow 25.8; Dublin 22.8.

The meteorological record for the week ending July 13, in Boston, was as follows, according to observations furnished b Sergeant J. W. Smith, of the United States Signal Corps: —

Week end'g Saturday, July 1889.	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.*			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U. S. ARMY, FROM JULY 13, 1889, TO JULY 19, 1889.

BRECHEMIN, LOUIS, Captain and Assistant Surgeon, U. S. A., by Par. 1, S. O. 159, A. G. O., July 12, 1889, ordered to Illinois National Guard, near Springfield, Ill., during remaining portion of encampment.

Leave of absence for fifteen days is granted Lieutenant R. R. BALL, Assistant Surgeon, U. S. Army. Par. 3, S. O. 87, Dept. of the Missouri, July 9, 1889.

By direction of the Secretary of War the extension of leave of absence on surgeon's certificate of disability granted Captain H. G. BUNTOX, Assistant Surgeon, in S. O. 22, January 26, 1889, from this office, is further extended two months on account of sickness. Par. 1, S. O. 162, A. G. O., July 16 1889.

IMS. F. J., Assistant Surgeon U. S. Army, now at Fort Lyon, Col., will proceed to camp near Oklahoma City, Ind. Terr., and report to the commanding officer for duty, relieving Captain W. C. Gorgas, Assistant Surgeon, who, when so relieved, is authorized to avail himself of the leave of absence granted him in Par. 2, S. O. 84, c. s. Dept. of the Missouri. Par. 1, S. O. 87, Dept. of Mo., July 9, 1889.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE FROM JUNE 10, 1889, TO JULY 13, 1889.

FESSENDEN, C. S. D., Surgeon. To proceed to Cairo, Ill., on special duty, July 8, 1889.

LONG, W. H., Surgeon. Granted leave of absence for twenty-eight days. June 18, 1889.

AUSTIN, H. W., Surgeon. To proceed to Cairo, Ill., on special duty, July 8, 1889.

IRWIN, FAIRFAX, Surgeon. Granted leave of absence for ten days. July 6, 1889.

MEAD, F. W., Passed Assistant Surgeon. Granted leave of absence for thirty days. June 24, 1889.

MAGRUDER, G. M., Assistant Surgeon. Relieved from duty at Baltimore, Md., to report to the Supervising Surgeon-General for duty as Acting Chief Clerk and Attending Surgeon. July 10, 1889.

GOODWIN, H. T., Assistant Surgeon. Granted leave of absence for thirty days. July 8, 1889.

SOCIETY NOTICE.

WHITE MOUNTAINS MEDICAL SOCIETY.

The semi-annual meeting of this Society will be held at Hanover, N. H., August 1 and 2, 1889, beginning at 3 P.M. of Thursday. The Connecticut River Valley and the White River Medical Societies have accepted an invitation to meet at the same time and place.

The Faculty of Dartmouth Medical College have consented to take leading parts in the exercises of these meetings. They will speak, read papers on practical medical subjects, and will show and operate on cases if suitable ones are presented.

APPOINTMENT.

Dr. W. P. MANTON, of Detroit, has been appointed consulting Gynecologist to the Eastern Michigan Asylum.

BOOKS AND PAMPHLETS RECEIVED.

A Clinical Study of Paraldehyde and Sulphonal. By C. M. Hay, M.D. Reprint.

The Discovery. A Key to the Mysteries of Life. By J. D. Stillman, M.D., St. Louis, Mo.

First Annual Announcement of Tennessee Medical College, Knoxville, Tenn. Session 1889-90.

Annual Report of the Board of Health of the City of Lowell, for the year 1888. Lowell, Mass. 1889.

Annual Announcement and Catalogue of the College of Physicians and Surgeons. Baltimore, Md. 1889.

Les Agents Provocateurs de l'Hystérie. Par Georges Guinon. Publications du Progrès Médical. Paris. 1889.

The Student's Textbook of the Practice of Medicine. By Angel Money, M.D. Lond. London: H. K. Lewis. 1889.

STYRONE: A CONSIDERATION OF ITS VALUE AS AN ANTISEPTIC.

BY H. H. A. BEACH, M.D.,
Visiting Surgeon to the Massachusetts General Hospital.

THE addition of a new agent to the long list of antiseptics that have been employed, and are now being used, in the various departments of medical and surgical practice is not advised without hesitation. Observations in hospital and private practice, extending through a period of eleven years, warrant me in endorsing all that I claimed for styrone when announcing the discovery of its antiseptic properties to the Boston Society for Medical Observation in 1879. The scarcity of the drug, owing to the expense of its production, has been prohibitory of its general use, until now it enters the market as a comparatively new product at a reasonable cost. The origin of styrone (from liquid storax and balsam of Peru) suggests the reason for the employment and the effectiveness of the balsams in antiquated and modern surgical dressings.

Styrone, when used as an antiseptic, possesses three important advantages:

It is { 1st, Efficient
2d, Non-poisonous
3d, Agreeable in odor.

Surgeons of experience will admit the desirability of an agent offering adequate protection to a wound, and by competent tests proved to be without toxic properties. Lest the clinical tests of poisonous action, through absorption of the drug from dressing or the douching of cavities, should be insufficient, it has been given to dogs in doses of a fluid ounce with no unfavorable results. As a deodorizer of foul and offensive wounds or ulcers, particularly those associated with malignant disease or necrosed bone, it is as prompt, effectual and lasting as either of the poisonous or offensive smelling applications in common use. Its odor, not unlike that of cinnamon-water (U. S. P.), is worth the attention of surgeons who are using antiseptics near the head or face. In ulcerating cancerous growths it may be conveniently sprayed upon parts too sensitive to bear the douching necessary for clearing the surface of decomposing discharges. The following formula has been found useful in such cases, with the addition of morphine as required.

℞	Styrone	ʒi.	
	Glycerine	ʒi.	
	Distilled Water	ʒi.	M

To a raw surface, pure styrone is somewhat irritating; but in the form of an emulsion with olive oil, water or liquid vaseline, it may be applied freely to open wounds.

In the pleural and peritoneal cavities where the greatest opportunity is offered a *poisonous* antiseptic for absorption, styrone in solution[1] may be freely used without danger. One part to twelve, with water, is sufficiently strong to completely disinfect a foul and ulcerating surface.

In dentistry, I have the assurance of Dr. L. D. Shepard, formerly Professor of Operative Dentistry in the Harvard Dental School, and of Dr. C. A. Brackett, at present Professor of Dental Therapeutics, that they find it possessed of valuable antiseptic qualities and useful in their art. Dr. Brackett writes, "Styrone continues to be one of the agents upon which I place most reliance for correcting foul conditions in carious cavities and especially in the pulp canals of teeth . . . its odor is, for most patients and for myself, most agreeable."

I have never given styrone internally excepting to dogs. Its action upon the cholera bacillus is, however, so marked that a trial of it in cases of Asiatic cholera is indicated. It may yet corroborate the brilliant discovery of Koch, by killing the bacillus with which he explains cholera, and curing the patient. A solution 1–60, with a small proportion of glycerine added, tastes agreeably, and has a gently stimulating effect upon the mucous membrane of the mouth not unlike that of ginger syrup.

In the form of spray, using the following formula,

℞	Styrone	ʒi.	
	Glycerine	ʒi.	
	Distilled Water	ʒxxii.	M

I have known it to give great relief, with diminution of cough and expectoration, in a number of instances where the patients were subjects of phthisis, no other medicines being in use at the time. It may be substituted for carbolic acid in gargles requiring antiseptic action.

I have excised the female breast repeatedly, and after tying all vessels, washed out the resulting cavity with styrone and liquid vaseline (1–12), closed the wound with catgut sutures, enveloping the projecting ends of the drainage-tubes with a bunch of charpie as large as the fist, which had been saturated with the mixture and squeezed dry, then covering the wound with two layers of sheet-lint saturated with the mixture, overlapping the incision an inch on each side. A layer of borated cotton was afterward applied to maintain an even compression. Upon removal of the dressing at the end of eight or ten days, a good union without suppuration has been found. No unfavorable effects from its use have been observed in any instance.

The following case, copied from the hospital records, furnishes some evidence of its value as an antiseptic and of the freedom with which it may be used in the pleural cavity.

The patient was a young man, a student under the care of Dr. Seeyle, of Amherst, Mass. He had been in robust health up to April 25, 1888, when he developed the characteristic symptoms of pneumonia, with consolidation of the lower lobe of the left lung. An œdema of the right lung followed, and his condition became so critical that his life was despaired of for four days. His temperature was high, but controlled by 5 gr. to 7 gr. doses of antifebrin; pulse was rapid and feeble; respiration was rapid and shallow, with tracheal râles. Treatment (brandy, digitalis, carbonate of ammonia and atropia in $\frac{1}{100}$ gr. doses), lessened the œdema and relieved his breathing.

About May 1st, it was noticed that the heart-beat was well over on the right side of the sternum, and it has remained there ever since. This led to the belief that fluid had filled the left pleural cavity, though bronchial sounds were heard loudly as soon as he became a little stronger.

On May 4th, an aspirator-needle was inserted, and one-half pint of pus drawn off.

[1] 1–200, 1–100, or 1–50, with water, according to the requirements of the case.

On May 6th, about sixty-six ounces of pus were removed. Breathing then became easier, and the heart changed its position toward the left side.

On May 7th, sixteen ounces of pus removed by the aspirator.

On the 15th, 18th and 20th, from six to eight ounces were removed at each respiration; twelve ounces on the 22d.

Since the 15th, pus has not seemed to lie wholly in one cavity, but in pockets between the lung and chest-wall circumscribed by adhesions. Often the needle would strike nothing at one point but immediately after at a point one inch or more in any direction from the first puncture, ʒ i to ʒ vi would be found. Three or four points would be tried each day; and for the past ten days only two to three drachms have been removed from any one place, from some, nothing. For the past three weeks his temperature has ranged from 99.5° to 102.5°; pulse, from 120 to 140; respiration, from 25 to 40. Hoffman's anodyne relieves dyspnœa. Latterly, gtt. xii Majendie's solution morphia, twice daily, has afforded great relief. Brandy, ʒ ss, every three or four hours. Two quarts of milk, one or two egg-nogs daily; and for a tonic, tr. ferri chlor., acid phosp. dilut., and syr. ferric iod. For two or three days past pericardial friction sounds have sometimes been heard over right nipple.

May 28th, patient sent to the Massachusetts General Hospital. On entrance, general cyanosis; respiration very rapid and shallow; apex beat in fifth space, one inch outside of *right* nipple; slight systolic souffle at apex; flat throughout whole left chest; absent fremitus and feeble respiration; good resonance and respiration through whole right lung; a few coarse râles here and there; abdomen negative; urine highly acid, specific gravity 1027, no albumen, much sediment, urates. Liquid diet every two hours; carb. ammonia gr. v., and brandy ʒ ss, every two hours; tr. digitalis gtt. x, thrice daily; at 3 P. M., morphia subcutaneously, (½ grain), followed by relief of respiration and dyspnœa, and some sleep; at 6 P. M., another subcutaneous injection morphia.

May 29th, another subcutaneous injection morphia, ½ gr. at 4 A. M. Considerable cyanosis to-day and constant dyspnœa. Takes nourishment well. Transferred to surgical ward.

Dr. Beach saw him for the first time on the 29th and found his condition so serious (temperature 105°) that he explored the left chest immediately with the aspirator-needle in the ninth space, posterior axillary line, and withdrew one and a half pints of thick pus. When the cavity containing it had been exhausted, he punctured in the seventh space, and withdrew one and a half pints more. The cyanosis was much lessened, the patient breathed easier. The apex beat returned to a point inside of the right nipple, and there was good resonance over the left chest to the fifth rib.

On the following day his temperature was normal, color good, and respiration easy.

During the three following days the fluid began to accumulate again, and his temperature to rise once more. In anticipation of the previous experiences of the patient, Dr. Beach cut down upon the seventh rib, and made a resection which permitted free drainage, stitched a double tube in place, and washed out the cavity with a solution of styrone, 1 part to 200, afterward increasing the strength to 1–40.

On May 6th, the discharge was profuse but perfectly sweet; temperature normal; the lung has expanded; there is good respiration to the seventh rib in front; apex beat in stomach line; improving fast and gaining flesh. The discharge continued to diminish, and general improvement was constant.

July 9th, he was discharged well, the sinus entirely healed, and has gained twenty pounds since he entered the hospital.

Six months after, Dr. Seelye examined him, and pronounced him "in perfect health." He has gained in strength ever since he left the hospital.

In considering the strong germicidal properties of styrone, I have naturally been led to test its influence in hay-fever and rose-cold, knowing it to be a harmless and non-poisonous drug. Without wearying the reader by detailing many cases, I will simply add that it has been used sufficiently to prove that the marked relief and comfort following the use of spray containing styrone has been something more than a coincidence, whether or not the disease is due to the presence of micro-organisms. In not one case has it aggravated the symptoms. The following formula I have found useful as a spray for the nose and throat, used three or four times daily for five minutes, or more frequently, according to the severity of the case and the relief obtained each time:

℞	Styrone	gtt. x.
	Glycerine	ʒ ii.
	Water	ʒ iv. M
℞	Styrone	gtt. v.
	Liquid Vaseline	ʒ ii. M

The latter to be used with a vaseline spray-producer.

The appended report of Dr. Edward K. Dunham, Bacteriologist of the Massachusetts Board of Health, is corroborative of the above and of the microscopical observations made by me, in 1879, of the power of styrone in restricting the growth of some micro-organisms. I am under many obligations to him for the skilful and painstaking efforts he has made to reach the facts, and for arranging them in such attractive shape. They are published with his kind permission.

EXPERIMENTS WITH STYRONE, SULPHONAPHTHOL, EUCALYPTUS EXTRACT AND GLYCOBORON.

The method employed in studying the germicide value of these four reputed antiseptics consisted in subjecting cultures of bacteria to their action for definite periods of time, and then testing the cultures for living bacteria of the species originally present.

The species of bacteria chosen for these experiments were: bacillus anthracis, bacillus choleræ Asiaticæ (Koch), streptococcus pyogenes, staphylococcus pyogenes aureus, and a mixture obtained from a cold-water extract of beef which had undergone spontaneous putrefaction after exposure to the air.

The steps taken to put the above method into practice were as follows: Erlenmeyer flasks or test-tubes of sterile bouillon made from beef-water with the addition of one per cent. of Merk's *peptone carne sicc.* and one-half per cent. of table salt were inoculated with the bacterium on which the germicide action of the antiseptic was to be tried, and the culture allowed to develop until the bouillon was distinctly cloudy. A known proportion of the antiseptic was then added and thoroughly mixed with the culture. The mixture then stood either at the temperature of the room, or in the incubator, and at intervals little samples were

taken for examination with a sterile platinum loop. The amount taken for each test was about one-fiftieth of a cubic centimetre, which was transferred to a test-tube containing from five to eight cubic centimetres of sterile gelatine made of the same ingredients as the bouillon, with the addition of ten per cent. of Nelson's gelatine. The small quantity of antiseptic contained in the sample was therefore diluted with from 250 to 400 times its bulk of gelatine. The gelatine, after being thoroughly mixed with the sample was solidified on the inner surface of the test-tube so as to form a thin layer (Esmarch's "roll-tube"[2]). The roll-tubes were then set aside to develop, at the room temperature. Those in which no growth appeared were kept from one to five months, to exclude the chances of overlooking possible retarded or scanty growth.

These tests were made in duplicate; and, at the same time, a roll-tube of the micro-organism employed was made from a culture started at the same time, and like those treated with the antiseptic, but to which nothing had been added. This roll-tube served as a standard of comparison for the others, and made it possible to judge whether the antiseptic had retarded the growth of the bacteria.

A. Experiments with Styrone.

(1) On the Bacteria of Putrid Meat Water.

Minced beef was soaked twenty-four hours in twice its weight of cold water, strained, and the extract left exposed to the air for three days. Erlenmeyer flasks containing measured quantities of sterile bouillon were then inoculated with the putrid water, and allowed to develop for twenty-four hours. Definite proportions of styrone were then added, and the mixture preserved either at the room temperature, or at a constant temperature of 30 C. At intervals, roll-tubes were made with about one-fiftieth of a cubic centimetre of the mixture and five cubic centimetres of gelatine. Resulting growth in the roll-tubes, at the room temperature, was absent with three and one-third, two, one, and one-half of one per cent. acting through eight, twenty-four and fifty-two hours. One-third of one per cent. showed growth within the period of eight hours. At a temperature of 30° C., three and one-third, two, and four-fifths of one per cent. showed no growth in periods of eight, twenty four and fifty-two hours. One-third of one per cent. showed growth while acting eight and twenty-four hours, and one-sixth of one per cent. showed growth in the three experiments of eight, twenty-four, and fifty-two hours.

These results indicate that one-third of one per cent. is not sufficient to kill the ordinary putrefactive bacteria at the usual room temperatures. At a higher temperature the action of the styrone is a little stronger, but one-sixth of a per cent. does not destroy the bacteria even at a temperature of 30 C. (86 F).

(2) On Anthrax Spores.

Cleansed and sterilized silk threads were soaked in bouillon containing large numbers of disseminated anthrax spores obtained from potato cultures of anthrax grown at a constant temperature of 30° C. The threads were then quickly dried.

A number of these threads were placed in strong styrone. At intervals ranging from two minutes to twenty-six hours, two threads were taken out and placed in five centimetres of gelatine, and a roll-tube made. In every case an abundant growth of anthrax resulted, showing that styrone, even in full strength, is incapable of killing anthrax spores.

Another set of experiments similar to these was made with the saturated solution of styrone spoken of in the following paragraph. The results of these experiments were the same as those where styrone in full strength was used, showing that admixture of water with the styrone did not, in this case at least, increase its germicide action.

(3) On the Bacillus of Asiatic Cholera (Koch).

Eight test-tubes containing sterile bouillon were inoculated with the bacillus, and allowed to develop for twenty-four hours at a temperature of 35° C. To four of these tubes a quantity of a saturated solution of styrone, equal in bulk to the bouillon already present was added, and the tubes placed in a incubator at 35° C. From these tubes, and also from those not treated with styrone, samples were taken and roll-tubes prepared. In all the roll-tubes from the untreated cultures an abundant growth of the bacillus could be seen on the second day. From the tubes treated with styrone, samples were taken five minutes after the addition of the styrone, in two of the resulting roll-tubes no growth appeared, in the other two, there were 180 and 360 colonies respectively. Samples taken twenty-four hours after the addition of the styrone contained no living bacteria.

The saturated solution of styrone which was used in these experiments, and the following ones, was prepared by heating a slight excess of the styrone with tap-water until the water reached a boiling point, allowing the mixture to become cold, and then filtering through a moistened filter. In this way a perfectly clear and homogeneous solution was obtained. This method was employed in order to avoid the use of an emulsion which might be of widely varying strength.

(4) On the Streptococcus Pyogenes.

Fresh cultures of the streptococcus pyogenes were obtained from a metastatic abscess in the axilla. With this material a number of bouillon cultures were made, and, after forty-eight hours incubation at 36.5° C., treated with definite proportions of the saturated aqueous solution of styrone. Roll-tubes were then made as in the previous experiments, to test the cultures for viable streptococci. The results are given in the following table:

Styrone Sol.	100 %†	3 %†	6 %	9 %	12 %	15 %†	21 %	30 %
After 8 min.	****	..	..	..	..	..	..	..
" 1½ hrs.	0	****	..	..	..	**	..	..
" 2 "	..	****	****	****	****	**	*	*
" 4½ "	..	****	..	..	..	**	..	..
" 6 "	..	****	****	****	****	*	*	*
" 8 "	0	..	..	..	..	..	..	..
" 18 "	0	..	..	..	..	..	..	..

† Experiment made in quadruplicate, the others made in duplicate.

An attempt has been made in the above to indicate the relative number of colonies present in the roll-tubes, as compared with the number in a control roll-tube made from a culture of the streptococcus prepared at the same time and manner as those to which the styrone solution was added, but to which no styrone had been added. The growth in those roll-

[2] Zeitschr. f. Hygiene, Ed. I., 293.

tubes in which the number of colonies did not differ materially from that in the control is indicated with four asterisks, a considerably smaller number with three, and so on. The cultures were kept at a temperature of 36.5° C.

In order to determine whether the multiplication of the streptococcus would be inhibited by the addition of a smaller proportion of styrone than would be necessary to kill it, the following experiments were made. To test-tubes containing a known amount of agar-agar definite proportions of the styrone solution were added, and, after thorough mixture, the agar quickly solidified. These tubes were then inoculated with the streptococcus, and placed in the incubator at 36.5° C. At the same time a control culture was made to serve as a standard of comparison. Great pains were taken to have the amount of the bacterium used the same for all the tubes. The result of a comparison of the growth in the styrone-agar tubes, with that in the control-tube is given in the following table.

Styrone Sol.	0.8%	1.6%	2.4%	4%	5.6%	8%	12.5%	25%
After 24 hours,	****	****	****	****	****	****	0	0
" 7 days,	****	****	****	****	****	****	0	0

(5) On Staphylococcus Pyogenes Aureus.

This coccus was obtained in fresh culture from pus derived from an acute abscess. The experiments with it were parallel with those made with the streptococcus, and require no special description. The results of bouillon cultures of the staphylococcus treated with styrone solution at 36.5° C., are tabulated as follows:

Styrone Solution added	100%	60%
After 1½ hours	****	..
" 2 "	..	****
" 10 "	..	****
" 24 "	0	..

Agar-agar, containing definite proportions of styrone, was inoculated with the staphylococcus. Kept at a constant temperature of 36.5°, and compared with a control culture of the same age, the styrone solution of eight-tenths, one and six-tenths, two and four tenths, four, five and six-tenths, eight, twelve and five-tenths, and twenty-five per cent.. after twenty-four hours and seven days, showed in each case a growth in which the number of colonies did not differ materially from that in the control tube.

(6) On a Guinea Pig.

A guinea pig weighing 720 grammes, was fed, by means of a stomach-tube, with the saturated solution of styrone used in the foregoing experiments. The experiment was made three times, the dose being two cubic centimetres, five cubic centimetres, and ten cubic centimetres. In no case did any appreciable effect result.

B. Experiments with Sulphonaphthol.

(1) On Streptococcus Pyogenes.

Sulphonaphthol Solution added,	100%†	3%	15%
After 8 minutes	0	..	..
" 1½ hours	..	**	0
" 4½ "	..	**	0
" 24 "	0	..	..

† Experiment made in quadruplicate, the others in duplicate.

These experiments were similar to those made with styrone. The sulphonaphthol was used in a solution prepared by adding about three cubic centimetres of it to fifty cubic centimetres of water, heating to incipient boiling, cooling and filtering. Temperature 36.5° C.

To determine the inhibitory action of the sulphonapthol. Temperature 37°.

Sulphonaphthol Sol.	0.8%	1.6%	2.4%	4%	5.6%	8%

THE CLINICAL HISTORY OF ARSENICAL POISONING.[1]

BY A. F. HOLT, M.D., CAMBRIDGEPORT.

ARSENIC is by far the best known of all poisons, there being hardly a person in the community but what is familiar with its deadly properties. It can not only be had for the asking at nearly all the street corners, but it is even extensively advertised in the form of rat-poison and Paris-green for the destruction of potato-bugs. It is tasteless and odorless, and can readily be mixed with most kinds of food, both solid and liquid.

These facts, no doubt, in a large degree account for the almost daily occurrence of cases of arsenic poisoning both suicidal and homicidal. For the perpetration of both these crimes it is probably used oftener than all of the other poisons combined, and its use for such purposes is constantly increasing. In my own limited experience in the last four years, sixteen cases have occurred, nine of these were probably cases of murder, the remaining seven being suicides or attempted suicide.

The exceedingly common use of this substance for criminal purposes makes the subject of arsenical poisoning not only one of great interest to the medical jurist, but also one of which he must have a thorough and critical knowledge for a proper performance of his duties.

The first suspicions of a criminal case of poisoning with arsenic, and it is only with such that the medical examiner has to deal, are usually aroused at the bedside of the victim; and as such suspicions must often be confirmed or dispelled by the clinical history of the case alone, such a history becomes of great medico-legal importance. Such cases are, as a rule, fairly typical and well-marked, most of them following the same general course and presenting the same prominent symptoms. Unfortunately, however, some of the diseases that result from natural causes present the same general symptoms, and to distinguish between these is always difficult and often impossible.

[1] Read before the Massachusetts Medico-Legal Society, October 3, 1888.

No better evidence of this can be had than that presented by the notorious Robinson cases. Here were eight cases of criminal arsenical poisoning, seven of them occurring within a period of about five years in one family, and the other in a near relative. All of these cases were treated by physicians of large experience, most of whom are among the very best in our profession, men who, as careful and accurate observers, stand in the very front rank. Yet the real cause of the sickness and death of these victims was not even surmised until a chain of circumstances, unknown, of course, to the physicians, came to the knowledge of the associates of the Robinson family. There was no suspicion of arsenical poisoning in these cases, and nothing to excite such suspicion except the symptoms presented by the patients themselves, and these could readily and properly be accounted for by diseases of every-day occurrence.[2]

Reports of cases of arsenical poisoning are scattered through the medical journals that have been issued within the last forty or fifty years, and such reports comprise very largely the literature of this subject, so far as the clinical history of such poisoning is concerned. All kind of symptoms have been reported to result from an overdose of this substance.[3] Some medico-legal writers have divided these cases into periods, some of one time and some of another; while others have described them as acute and chronic; and the symptoms that are described by writers on the subject represent nearly all the ills that flesh is heir to. No one has attempted to reduce them to order, and I am sure no successful effort could be made to eliminate from them a clear and concise description of the clinical history of arsenical poisoning that would apply to all, or even a majority of such cases. No such effort to eliminate from the mass of symptoms ascribed to arsenic a clear and detailed description of such poisoning will be made in this paper, for the writer has had no better opportunities of observing cases of this sort than his predecessors, and only an attempt will be made to describe such symptoms as will probably occur in such cases, and the order in which they appear, symptoms that should at least

[2] There has been a good deal of adverse criticism, not only on the part of the community at large, but in the public press, both as items of news and in editorials, because the physicians in attendance on these cases did not discover their real cause, or at least have their suspicions aroused. The general impression is that they were all treated, or at least most of them, by the same physicians. This, of course, was not the fact. The guilty mother was very careful not to employ the same physician twice; and, in ordering a consultant, she always sent for a different one each time. Not only this, but no more than two of the victims died in one house or one neighborhood. But even had one physician treated them all, his suspicions might not have been aroused. There never was a breath of suspicion on the part of the friends of the Robinson family, who must, of course, have known of all the deaths and the circumstances surrounding their occurrence. As the sickness of these unfortunate people was like that of diseases from other causes than arsenic, diseases, too, of common occurrence, why should the suspicions of the physicians have been aroused more than that of the friends? Doctors are not looking for a murderer behind the door of every house they enter, where there is vomiting, purging and other gastric disturbances the cause of which does not readily appear. A physician who has no more faith in humanity than this, has certainly mistaken his calling, and such an one would be unworthy of confidence or respect.

The people and the press that have made these unjust criticisms forget that cases of poisoning with opium, strychnia, the strong acids, and, in fact, those produced by all the other poisonous substances, are almost invariably detected at once by the physician, even if he has never seen a case of poisoning. The reason of this, of course, is, the symptoms produced by most poisons are clearly defined and distinctive, while those produced by arsenic are not so, but are like those produced by many other causes.

[3] Many unquestionably, even if not a large majority, of the cases of arsenical poisoning that have been reported in the medical journals were observed by men little used to habits of close observation, and less to recording what they saw, and this fact may account for some of the symptoms that have been referred to arsenic; still there can be no question but what under different circumstances of administration, and in different individuals, the results may be variable and widely different in different cases.

arouse our suspicions of arsenic poisoning where they cannot be clearly and definitely accounted for in some other way.

Arsenic is both a narcotic and irritant poison: sometimes one set of symptoms and sometimes the other, may prevail. It has a specific effect upon the mucous lining of the stomach and bowels, and this effect is produced whether the poison is swallowed or administered in some other way, as for instance, where a considerable quantity is applied to an ulcerated surface.

The time between the taking of a poisonous dose of arsenic and the occurrence of the first symptoms is variably stated as being from a few minutes to sixteen hours, depending upon the condition of the stomach. The real cause of the great difference in time in producing poisonous effects is, I believe, largely due to the sparing solubility of arsenious acid (the form in which this poison is usually taken). If, for example, the stomach is covered with mucus, or contains some mucilaginous material with but little water, or if it contained semi-solid food of any kind, the crystals of arsenic might readily become imbedded in it and remain for a considerable period before enough would be dissolved to produce poisonous effects. The usual time for the first evidences of the effect of the poison to appear is from half an hour to an hour. They are rarely delayed more than two hours, and almost never appear sooner than twenty minutes. A single case has been reported where the vomiting and pain occurred almost as soon as the poison was swallowed.

The symptoms of arsenical poisoning as given by one author are as follows: "The symptoms produced by the poison are an austere taste; fetid state of the mouth; frequent ptyalism; continual hawking; constriction of the pharynx and œsophagus; the sensation of the teeth being on edge; hiccough; nausea; anxiety; frequent sinkings; burning pain at the præcordia; inflammation of the lips, tongue, palate, throat, bronchi, and œsophagus; irritable stomach, so as not to be able to support the blandest drinks; vomiting of matter, sometimes brown, at other times bloody; black, horribly fetid stools; small, frequent, concentrated and irregular pulse, but occasionally slow and unequal; palpitations; syncope; insatiable thirst; burning heat over the whole body, or a sensation of icy coldness; difficult respiration; cold sweats; suppression of urine; scanty, red, bloody and sometimes albuminous urine; change in the countenance; a livid circle around the eyelids; swelling and itching of the body; livid spots over the surface, and occasionally a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium; convulsions, often accompanied with insupportable priapism; falling off of the hair, detachment of the cuticle, etc. In some cases there is inflammation with burning pain in the urino-genital organs. Occasionally the symptoms have a perfect resemblance to those of Asiatic cholera, in a stage of collapse." This author further says: "It is very rare to observe all these symptoms in a single individual," and, "that sometimes they are nearly all wanting, death taking place without any pain or prominent symptom."

From such a confused mass of symptoms as these, indicating disturbance in every part and every vital organ of the body, and these perhaps presented in all conceivable combinations with nothing else to arouse his suspicions of arsenic poisoning except the condition of his patient, how is the physician at the bedside to determine that the case with which he is dealing is one of arsenic poisoning? or how is he to have his suspicions aroused in this direction? Certainly not from arranging in his mind, and keeping before him for instant use, such a confused mass of ills as are here enumerated, as such an attempt could only lead to failure, but rather, I believe, by the careful consideration of the prominent symptoms produced by arsenic, and the order in which they occur.

The first symptom that occurs in these cases and one that all agree is usually present, is a feeling of faintness or weakness. This comes on in a half-hour or an hour after swallowing the poison, and continues until the more marked symptoms are manifest. This faintness is, I believe, from the physiological effect of the poison. The next prominent symptom, and one, too, that is almost always present, the exceptions being very rare, is vomiting. This usually occurs in from a half-hour to two hours of the ingestion of the arsenic. Occasionally this symptom is delayed; but the above rule would, I believe, include nine-tenths of these cases. The vomiting is violent and incessant, almost always continuing, if the case proves fatal, until death. The vomitus, after the stomach has been first emptied of its contents, consists of a watery secretion mixed with glairy mucus, bile and sometimes streaks of blood. This vomiting is almost sure to occur whenever anything is taken into the stomach. It is accompanied by a severe and pretty constant retching and a burning pain. The pain is referred to the region of the stomach and lower part of the chest. In one case that came under my observation, the patient complained that "she was burning up inside."

Pain in the stomach and vicinity is one of the most marked signs of arsenic poisoning, and is rarely absent: usually it is of the burning character above referred to. This continues to the end. Another pronounced symptom is dryness of the throat and mouth, and great thirst. The patient is constantly calling for water, although he knows that the drinking is sure to excite vomiting. The next prominent symptom to appear, and one that is almost always present also, is the great tenderness on pressure over the region of the stomach. This tenderness is usually very acute, the patient often crying out at the least touch. This symptom is, I believe, one of the most typical of arsenic poisoning. It does, of course, occur in other forms of gastric irritation, but generally it is not so acute, and such cases almost invariably have a very different history. This acute tenderness accompanied by vomiting, pain and thirst, coming on suddenly in the absence of any known cause, should be considered good ground for suspicion, at least of metalic poisoning.

The next prominent symptom is diarrhœa. This occurs in from one to three hours. The stools are at first yellowish and very loose, afterwards they may become watery and at times bloody. Often there is great and continuous tenesmus, with only the discharge of a little blood. This symptom of looseness of the bowels is not always present. In two cases that came under my observation, there was no discharge from the bowels; both of these terminated fatally in about eight hours. In another case, that of a girl sixteen years of age, a profuse watery diarrhœa came on soon after the vomiting, and continued up to within an hour of her death, which occurred in about six hours from the commencement of the poisoning.

The above symptoms usually continue from two to

five or six hours, when the pulse becomes quick and feeble, the skin cold and clammy, and perhaps covered with profuse perspiration; the face is pinched; in a word, the victim falls into a state of collapse, in which he may remain for some hours, death usually occurring however, in from five to ten hours after the ingestion of the poison. During the last hours of life there is often cramps (particularly in the legs and arms), low delirium, coma and sometimes convulsions. In some of these cases these symptoms continue twenty-four hours, and rarely longer, although all authors agree that a very large proportion of them terminate in nine or ten hours. In cases where the death is deferred four or five days, the vomiting continues, particularly when anything is taken into the stomach. The skin is dry and hot, and after a day or two becomes sallow and sometimes jaundiced; the eyes yellow; the tongue dry and cracked; and the lips and gums bleed readily. The pulse is small and quick; the stomach and bowels are distended and tender; the urine is diminished in quantity, and often contains a large amount of albumen; the cheeks are sunken; there is often delirium and great prostration; until at last the patient sinks into a state of collapse, as in the more acute cases, and dies.

This class of cases is much more likely to escape detection than those where death occurs in a few hours, as the effects are much less pronounced, and some of the symptoms may be absent, or so slight as to attract but little attention. Often there is little or no appearance of a fatal issue for the first two or three days, or until the fatty changes in the liver and kidneys has seriously complicated the case by bringing about a series of symptoms, the result of such changes.

In another class of cases the poison seems to act as a narcotic, the victim complaining of little or no pain or nausea, but sinks into a sound sleep, soon becomes comatose, sometimes convulsed, and in a short time dies. It is this class of cases, and those that rapidly fall into a state of collapse after the pain and vomiting appears, that are the most speedily fatal.

In five cases of which I have had intimate knowledge, they have all died in less than nine hours from the inception of the poisoning. In three other cases of poisoning with Paris-green, used for the destruction of potato-bugs, recovery took place, although in one case more than a dessert-spoonful was swallowed; the explanation of this escape probably being, that the stuff called Paris-green used by the farmers, is made up largely of adulterations. The other ten cases that have come under my observation, including the Robinson cases, have lived from five days to six weeks from the time evidences of poisoning were first observed. These deaths were all homicides, and in eight of them the poison was administered by one hand. It is certainly very extraordinary that all of these cases should so widely differ, so far as the deaths are concerned, from the usual rule in cases of arsenical poisoning. In some of these, undoubtedly, the dose was repeated, and perhaps more than once. To me there is no more remarkable fact connected with this notorious series of crimes (the Robinson cases) than this one. How a woman, ignorant of the effects of arsenic except to know that it was a poison, could so graduate the dose in eight successive cases as to delay the fatal issue from six days to six weeks, is beyond comprehension. It was undoubtedly this anomalous result that enabled her to conceal her crime so successfully. One of the deaths was certified as caused by pneumonia, one by typhoid fever, one by meningitis, one by bowel disease, and one by kidney disease.[4] Had the clinical history of one of these cases been the usual one of arsenical poisoning, with a fatal issue, it is more than probable that the real cause of death would have been detected. The causes of death in arsenic poisoning are the physiological effect of the drug, shock, and irritation of the intestinal canal and other organs. It may be from one of these alone, or from two, or from all of them combined. Cases of death that occurred from this cause within one hour of the poisoning, or even those that occur later, where no irritant effects have been observed, are from the physiological effect of arsenic; those occurring later, and within eight or nine hours are usually from the physiological effect and shock; while those that occur in three or four days are from irritation and the consequent inflammation, perhaps combined with physiological effects on the liver and kidneys. The diseases that may simulate arsenic poisoning are cholera morbus, colic with vomiting and gastric irritation from other causes. The points of distinction between these and arsenic poisoning, so far as their prominent symptoms are concerned are not well-marked; still, when the whole history of a case of either of these ailments is carefully compared with one of arsenic poisoning following the usual course, there usually are points of sufficient difference to enable one to make a differential diagnosis with a tolerable degree of certainty. For instance, the pain of colic or cholera morbus is usually paroxysmal and griping, or hard; while the pain of arsenic is burning and continuous. There is not often tenderness in either of the former, while this is a well-marked symptom of the latter. The vomiting of arsenical poisoning almost always is the first serious symptom; and this (and the retching) is continuous, or is repeated at short intervals; while that of cholera morbus and colic, if it occurs at all in the latter, comes on later, the pain almost invariably preceding it.

Thirst is a prominent symptom in arsenic poisoning while it is often absent in cholera morbus and colic. The diarrhœa of arsenic comes on after the other symptoms are well established; in the diseases we are considering, it is often the first sign of disturbance. Cholera morbus and colic usually respond readily to remedies, the pain and vomiting ceasing; and health is rapidly restored. And they are almost never fatal, except in the old and feeble; while, in arsenic poisoning, the case goes on from bad to worse, in spite of treatment, to a fatal issue. Therefore, the severity of symptoms is another of the cardinal points in differential diagnosis. Cases of gastric irritation of severe type, may, under certain circumstances simulate arsenic poisoning very closely; but fortunately such severe irritations are of rare occurrence, and usually they can be traced to some well-marked and definite cause. Cases where such well-marked cause does not appear should at once arouse suspicion of metallic poisoning. In such cases, where the vomiting continues without apparent cause, the settlings of vomitus should be examined for crystals of arsenic, and sent to

[4] It perhaps should be further stated that in all of these cases the guilty mother selected a time to administer the poison when they were sick. For example, the sister had been suffering nearly a week with pneumonia before Mrs. Robinson saw her; the husband, whose case was supposed to be one of typhoid fever, came home from Boston suffering so severely with pain, nausea and vomiting that a physician was at once sent for; while Willie, the last victim, was under medical treatment from the result of a fall.

a chemist for analysis. This matter, however, belongs to the medico-legal considerations of arsenic poisoning rather than to its clinical history.

In cases of arsenic poisoning where death does not occur for some days, the prominent symptoms, as has already been said, are usually less well-marked: consequently the diagnosis is more difficult. Such cases can only be determined by a careful consideration of their histories and surroundings, examination of the vomitus for crystals of arsenic, and chemical analysis of the urine, as this poison is largely eliminated by the kidneys.

Chronic arsenical poisoning occurs occasionally from the repeated administration of small doses, although there is little likelihood of this being attempted for purposes of crime, except possibly by one thoroughly familiar with its action. These cases may present all the symptoms of the acute form of poisoning, although usually in a mild degree; and to these may be added extreme nervousness, trembling, paralysis (particularly of the hands or feet), tingling in the fingers and toes, a vesicular eruption on the body or limbs, suffusion of the eyes, ulceration of the mouth, jaundice, strangury, etc. The patient becomes emaciated, prostrated, and finally dies from exhaustion, or disease of the kidneys. One of the Robinson cases was of this kind, the patient, a girl twenty-two years of age, living six weeks after the first symptoms of poisoning showed themselves. In this case there was paralysis of both feet, and the urine contained albumen and casts.

As has been already said, there are no distinctive symptoms of arsenic poisoning, and one can only be certain he is dealing with such a case when the poison is found in the vomitus or urine, or there is other proof that it has been administered. The physician should be reasonably alert in trying to determine the causes of cases that come under his observation where there is vomiting, purging, pain, etc.; but it is no part of his duty to suppose that all such cases are the result of metallic poisoning.

LATENCY OF ATAXIC SYMPTOMS IN CASES OF OPTIC ATROPHY.[1]

BY G. L. WALTON, M.D.
Clinical Instructor in Diseases of the Nervous System, Harvard University.

IT has been long noted that optic atrophy, when present in locomotor ataxia, appears generally among the earlier symptoms. Indeed, given a case of optic atrophy without recognizable cause, the chances are altogether in favor of characteristic pains, bladder irregularities, or other symptoms, appearing later, which, even if not marked, will enable us to place the case under this category.

Charcot[2] emphasizes the fact that most women coming to the hospital with amaurosis develop sooner or later, in the majority of cases, ataxic symptoms, perhaps ten, perhaps fifteen years later. In one case cited, the blindness was followed in ten years by shooting pains and girdle pains, these symptoms remaining stationary for ten years more, when appeared symptoms of muscular incoördination.

Gowers[3] mentions cases of his own in which optic atrophy preceded ataxia by sixteen and twenty years, and quotes a case reported by Buzzard,[4] in which atrophy existed fifteen years, associated only with lightning pains and loss of knee-jerk.

In his recent text-book, Gowers[5] has stated that atrophy of the optic nerve so universally appears early in the disease, that, after the ataxic gait is fairly established, it is of rare occurrence. Conversely, he states that when optic atrophy has become developed, it is common for the other symptoms of locomotor ataxia to remain in abeyance. To use his own words, "In a large number of cases, the ataxia never comes on, the spinal malady becoming stationary when the nerve suffers." If this is true, its bearing on the question of prognosis is of considerable import. It is certainly something to be able to assure a patient, at any stage of this disease, of his probable, or even possible, immunity from any of its distressing symptoms. In the matter of diagnosis, also, the subject is worthy of consideration.

I have looked through the records of sixty-six consecutive cases of locomotor ataxia, — fifty-two seen in the Neurological department of the Massachusetts General Hospital, and fourteen in private practice, — in the hopes of throwing additional light on this branch of the subject. The result is as follows: Out of the sixty-six cases, the diagnosis optic atrophy was found in fourteen; and six more had decided loss of eyesight. In these six there was no description of the optic nerve given in the notes, which prevents their being classed with certainty under the cases of atrophy, although undoubtedly some, and perhaps all, of them belong there. Out of the fourteen cases of optic atrophy, the degree of incoördination was mentioned in eleven. In three of these eleven, there was no ataxia; in five, it was slight; in three only was there marked ataxia. In the eight cases in which the ataxia was slight or wanting, the duration of the disease was respectively, two, three, four, seven, eight, ten, twelve and twelve years. In nine of these fourteen cases, the knee-jerk was noticed. It was present in one or both legs, in four out of the nine; and in one other case, where the loss of eyesight was so considerable as to leave little doubt that optic atrophy was present, the knee-jerks were normal. In all of the cases the disease was well advanced. These figures, while far too incomplete to be regarded as statistical, are still of some interest, sufficiently so to encourage further investigation.

The noticeable features are the large proportion of cases in which the knee-jerk was retained in one or both sides, and the large proportion in which ataxia was either absent or very slight. With regard to the ataxia, this has been already considered by neurologists as a symptom not necessary to the diagnosis, hence the tendency to restore the name "tabes dorsalis" in preference to locomotor ataxia. The point to which I would call attention is that to which Gowers has practically alluded, namely, that it is the cases in which optic atrophy is present in which we may expect to find the absence or indefinite postponement of ataxia. Again, with regard to the preservation of the knee-jerk, the loss of knee-jerk in locomotor ataxia is, as a rule, one of the earliest and most constant symptoms, a fact which lends considerable significance to its preservation in four out of nine (probably five out of ten)

cases where optic atrophy was present. The practical bearing of these facts is to assist us in both diagnosis and prognosis. As regards diagnosis, they would lead us to place with confidence under the head of locomotor ataxia certain cases of optic atrophy which we may have hesitated to place there on account of the presence of knee-jerk and absence of ataxia. As regards prognosis, they would lead us to predict a comparative latency of the motor symptoms of the disease where optic atrophy has become pronounced.

The constancy of one symptom was noticeable in the cases with optic atrophy as in those without it, namely, the Argyle-Robertson pupil. This symptom, together with characteristic pains, may, it seems, be looked for early in this class of cases, however latent the motor symptoms. If the Argyle-Robertson pupil were dependent on optic atrophy, it would be expected particularly in these cases; but its constancy in the other cases shows it to be independent, at least in general, of the lack of conducting power in the optic nerve, a fact already well recognized.

It is worthy of note, that, out of sixty-six cases taken indiscriminately, there were fourteen with the diagnosis of optic atrophy, and several more in which it was probably present. Statistics on this point vary greatly. Erb found eight cases in about seventy, while Topinard noted disturbance of vision in forty-nine out of one hundred and two, and Cyon found sixty cases with amblyopia and amaurosis out of two hundred and three. The statistics of more recent observers also vary markedly. The figures of oculists would naturally run higher than those of neurologists. Gowers states that the proportion is much less than is generally believed, certainly not exceeding one case in ten.

I have selected three cases to report this evening, premising that they are presented, not as being in any way unique, but as fairly representing the class of cases under consideration.

CASE I. J. C., aged forty, married, an engraver. Referred to me at the Massachusetts General Hospital, by Dr. Standish, under whose care he is at present. Four years ago he began to suffer from recurring pains in both knee-caps, without swelling or redness, and not increased by movement. He describes the pains as shooting and stinging, lasting only a few minutes. Similar pains appeared later in the thigh and in the toes of the left foot. Six months ago he noticed failure of eyesight, which rapidly progressed to almost complete blindness within three months. There have been bladder irregularities, but no absolute incontinence. There have been no laryngeal nor gastric crises. He tires easily in going up stairs, and has done so for four or five years. He has never noticed any staggering or numbness. He never saw double.

Physical examination shows absence of tendon reflex on the left, a trace on the right. Both pupils react to accommodation, neither to light. Both pupils are small, the left smaller than the right (said by the patient always to have been so). There is no trace of impairment of any variety of sensation, not excepting muscle sense. There is no special loss of nutrition. The gait is perfect, and the patient stands on either foot without swaying, also with both feet together and the eyes shut. Ohpthalmoscopic examination by Dr. Standish, as well as by Dr. Wadsworth, who saw him at the hospital, shows characteristic optic atrophy. The vision is now so reduced that he can only count fingers with the right eye at four feet; vision in the left eye being 0.4, not improved by convex or concave glasses.

CASE II. Mr. ——, aged forty-seven, married. Referred to me for examination by Dr. Chandler. He has also been examined by Dr. Wadsworth and Dr. Prince. Has had weakness and pains in the back since 1864, when he was injured by the blowing up of a vessel. He first noticed trouble in sight in 1879, which increased steadily. He can now with the left eye, barely count fingers at a foot: with the right eye, there is perception of light only. Since 1882 he has had pains, sometimes very severe, perhaps three or four a year; lighter attacks of pain often, lasting ten or twelve days. These pains are generally in the back of the legs and in the hips. During the past eight or nine years a pain runs up the back to the head. This pain comes quickly and recurs perhaps a dozen times a day. Sharp, throbbing pains appear in the legs, lasting from an hour or two to several days. The locality of these pains varies; for example, one day in one foot, one day in the other, again about the knee, no swelling or redness accompanying the pains. In 1885, he saw double for six weeks. There has been no bladder trouble, no laryngeal or gastric crisis, no numbness, nor weakness in the legs; occasionally a slight tendency to stagger. Twelve years ago he had what was considered a chancre, not followed by eruption or falling out of hair.

Physical examination shows the knee-jerk absent in the right, present in the left. There is no swaying with the feet together and eyes shut. He stands well on either foot with the eyes open, and fairly well on each foot with them shut (which is a difficult test). The lightest touch is felt everywhere. The plantar reflex is present. The right calf measures 15¼ inches, the left 15⅝ inches. The right pupil is larger than the left; neither reacts to light, both to accommodation. There is external strabismus in the right eye. The left field is cut off nearly to the horizontal meridian, and moderately contracted in other directions. Ophthalmoscopic examinations by Drs. Wadsworth and Chandler shows gray atrophy of the optic nerve, more pronounced in the right. The pulse is 106. There is no scar on the penis, but the frænum is wanting (said to have been burnt off).

CASE III. A. D., aged thirty-one. Referred to me for an opinion by Dr. Chandler, and afterwards by his attending physician, Dr. Cutter, of Leominster. He has also been examined by Dr. Knapp. He first noticed trouble in sight seven years ago, and has steadily lost vision up to the present. The only other symptoms complained of, are occasional pains in legs and feet, occasional dizziness, occasional attacks of gastric pain and vomiting (crises?), and a tendency to tire rather easily, with occasional slight unsteadiness. He also states that his water occasionally escapes, and that he sometimes holds it all day without desiring to pass it. There is no definite specific history, but he states that there was considerable falling out of hair after an attack of gonorrhœa twelve years ago. No sore was noticed, and no other secondary symptom.

Physical examination: There is a slight trace of knee-jerk on the left, none on the right. The pupils are unequal, and react to accommodation, not to light. There is no impairment of sensation; no wasting; slight ataxia. Dr. Chandler finds marked optic

atrophy. With the right eye he cannot count fingers. The vision in the left eye is .9.

In these cases will be noted not only absence or partial absence, of ataxia, but also that of sensory impairment, at a stage when these symptoms would be expected. It will also be noted that the knee-jerk was not entirely lost in either of the three cases. It is also noticeable that nutrition is unaffected, the patient in one case (Case III) especially, being a stout, well-nourished man, with calves measuring over fifteen inches. This is an exceptional condition in well-advanced locomotor ataxia, although this disease is not characterized by distinct wasting of muscles and groups of muscles, as are diseases affecting the peripheral nerves or the anterior cornua of the cord. The importance of these points in diagnosis is illustrated by the fact, that in two of the cases, considerable doubt has arisen in the minds of consultants as to the nature of the underlying cause of the optic atrophy.

Acting upon the suggestion offered by Dr. Webber in the discussion of this paper, I append a brief abstract of the symptoms in the cases of optic atrophy.

CASE IV. M. R. Numbness and darting pains for two years; delayed micturition; knee-jerk absent; pupils unlike. Argyle-Robertson pupils; pulse 102; vision blurred, field normal; discs opaque, with sharply defined vessels, especially right.

CASE V. T. M. Atrophy of optic nerve, twelve years; staggering during past eight weeks; Argyle-Robertson pupils; knee-jerk normal. During seven or eight years, beginning about fifteen years ago, patient was subject to attacks of vomiting about twice a week.

CASE VI. Pains, twelve years; pupils unlike, Argyle-Robertson pupils; knee-jerk absent; slight staggering with closed eyes; optic atrophy, (*b*) V = $\frac{1}{10}$ (*b*).

CASE VII. A. F. Darting pains in legs, seven years; bladder troubles, one year; diplopia and loss of sight, seven years; complete blindness, two and one-half years; vomiting, six years; pupils unlike, Argyle-Robertson; knee-jerk absent; slight ataxia; no anæsthesia.

CASE VIII. C. G. (female). Pains, eight years; failing sight, eight months; bladder irregularities; Argyle-Robertson pupils; loss muscle sense and slight loss tactile sense in middle toes (b); slight unsteadiness; stands fairly well with feet together and eyes shut; ophthalmoscopic examination by Dr. H. W. Bradford shows optic atrophy of both eyes.

CASE IX. W. F. B. (female). Shooting pains, seven years; weakness in legs, several years; staggering, one year; loss of muscle sense; loss of vision, one year; cannot count fingers with left eye; with right eye, vision one-third.

CASE X. N. B. Pains and ataxia, two years; loss of sight lately; knee-jerk absent; tabetic knee joint; slight optic atrophy.

CASE XI. P. C. Pains, a number of years; slight failing, two years; slight bladder irregularities; vision almost lost in left eye, greatly diminished in the right; color sense almost absent (cannot distinguish light blue from red even in the centre of the field).

CASE XII. C. F. Pains in legs; Argyle-Robertson pupils; pupils unlike; scarcely any ataxia with eyes closed; well-marked atrophy of optic nerves.

CASE XIII. F. K. Failing sight, two or three years; now, perception of light only; pains one year; Argyle-Robertson pupils.

CASE XIV. Gradual failing sight, one year; Argyle-Robertson pupils; pupils small; very slight ataxia; shooting pains in legs; well nourished; knee-jerks absent; marked optic atrophy both; (V. O. D. = $\frac{1}{50}$ V. O. S. $\frac{2}{10}$) nerves white; edges of disc well defined; retinal arteries and veins decreased (Dr. Cheney).

The description of the optic nerves in a few of these cases is such as to leave the diagnosis not absolutely certain. In the majority, however, the loss of sight is too great to admit of question. Whatever may be deducted from the number on account of uncertainty may be offset by the cases in which complete records are wanting, and among which exist, probably, certain cases of atrophy. In any event, the character of the investigation precludes reaching absolute statistics.

DEMENTIA FOLLOWING ETHER.[1]

BY JOHN HOMANS, 2nd, M.D.

MANIA subsequent to an injury or surgical operation has long been recognized, — an article on the subject having been written by A. Schroetter in 1804, — but, as a rule, was supposed to occur in alcoholic subjects or in those with diseased kidneys. Within a few years also, cases of mental disturbance following a surgical operation have been attributed to the antiseptic used, as iodoform or a strong solution of corrosive sublimate. Operations on the genital tract in women have occasionally been followed by mania; but here the cause may properly be found in the peculiar sensitiveness of the female genitalia to surgical interference, a case in point being one of sub-acute mania following the introduction of a speculum.

The object of this paper is to put on record two cases in which the mania seems to have been largely due to the administration of ether, as none of the above-mentioned factors were present. My attention was first called to this subject when a house pupil in the Massachusetts General Hospital by the first case to be reported, and latterly by an able paper by Dr. G. H. Savage,[2] which presents a careful study of the subject, and in which he classifies his cases into acute and sub-acute. The two cases which I present fall into the latter or sub-acute form.

The first case is that of a domestic, thirty-five years old, of a nervous temperament, who was operated upon at the Massachusetts General Hospital, in 1881, for cancer of the breast. The operation, history and appearance of the patient presented nothing extraordinary. The second case was a single lady of over fifty, suffering under the uric acid diathesis, and belonging to a somewhat nervous family who, in 1884, underwent the ordinary operation for fistula in ano. The cerebral symptoms appearing after the operation were so nearly similar in both cases that I present them together, the only difference between the two being that of the time at which the various symptoms appeared or disappeared, and that difference only a few hours, or, in the ultimate recovery, a day or two.

The history of these patients after the operation

[1] Read before the Boston Society for Medical Improvement, April 8, 1889.

[2] Brit. Med. Jour., December, 1887.

was as follows: For two days, a condition of euthanasia; patient remarkably happy and comfortable; no pain or discomfort; slightly flushed face; pulse and temperature only slightly raised above normal. On third day, patient a little excited; mind wandered a little, which condition increased till, on fifth day after the operation, the mind was completely gone; patient tried to get out of bed, or tear off the dressings, and constantly talked or muttered to herself, but with a mild, disconnected delirium, no especial delusions being noted. This condition lasted for about a week, when a gradual improvement began; and in about five weeks after operation the mind was perfectly clear. The first case died in a year or two of recurrence of the cancer, but without any mental trouble. The second patient is now alive and well, both physically and mentally. Here, then, are two cases, both women with somewhat neurotic tendencies, falling into the same demented condition after a not especially severe operation, and both recovering at about the same time.

That delirium tremens or mania sometimes follows surgical injury in alcoholic subjects is almost a medical axiom, and the temporary effect of ether is much the same as that of alcohol. We often tell the friends of a patient recovering from ether that they are not to mind what he says, because he will "talk just as if he was drunk." The physiological disturbances produced by the two drugs being somewhat the same, it seems a reasonable conclusion that their exhibition may give rise to true pathological conditions which strongly resemble each other. The use of drugs other than these two occasionally produces mania, as belladona, a case being mentioned by Dr. Savage in the paper above mentioned. In view of these various facts, therefore, I think it is justifiable to ascribe the prime cause of the dementia in these two cases to the inhalation of ether, other factors being the nervous family history or temperament. It would not be wise to base any strong statement upon a few cases; but I think the surgeon about to operate on a neurasthenic patient should bear in mind the possibility of an attack of mania, accompanied, fortunately, by the probability of a complete recovery.

REPORT OF PROGRESS IN GYNECOLOGY.

BY F. H. DAVENPORT, M.D.,
Assistant in Gynecology, Harvard Medical School.

OPEN FALLOPIAN TUBES.

DR. JOHN WALLACE[1] has gradually come to the conclusion, that not only is the open condition of the Fallopian tube more common than is usually thought, but that it may be a normal post-partum condition just as subinvolution is, and that like that it only gives rise to symptoms when its return to a normal state is arrested. The tubes and ligaments generally increase in size markedly during pregnancy, and anything which retards their perfect involution, such as tight bandaging after labor, permitting the patient to rise too soon, tight lacing or heavy petticoats may result in a more or less patulous condition of the ostium uterinum of the oviducts. As symptoms of this condition, the author notes abdominal pain, numbness, cramps, bearing down, frequent micturition, and pressure upon the rectum. Physical examination shows a congested and œdematous cervix, uterus prolapsed or retroverted, and a profuse discharge of ropy, yellowish mucus. One or both ovaries or tubes are apt to be found in the retro-uterine pouch. A uterine sound may, with a little gentle manipulation, be made to enter the tube, and be passed up to the hilt. This manipulation causes little pain, and is an important part of the treatment.

The treatment in general is prolonged, and consists in rest in bed, hot douches, adjustment of pessary (if possible), catheterizing the tube once a week, and intra-uterine applications. The author gives a list of fifty-three cases in which he found this condition, all of which were cured.

[While we allow that this patulous condition of the tubes following parturition may be common, yet we fail to see that the symptoms the author describes are attributable to the state of the tubes. They are the common symptoms of subinvolution of the uterus. The open tubes seem to us merely a coincidence, and their catheterization not only unnecessary but even hazardous.— REP.]

RAPID CURATIVE TREATMENT OF CYSTITIS IN WOMEN.

Dr. T. More Madden[2] refers to the prevalence of cystitis in women, and after a brief synopsis of the causes, symptoms, and general treatment, which contains nothing especially new, describes the method of radical cure which he has employed in chronic cases. He thoroughly dilates the urethra with a specially devised instrument, so as to admit the index finger, and for a time completely paralyze the sphincter. In some instances, he uses a dull wire curette to remove the proliferating vesical mucous membrane. In every case, he makes an application of carbolic acid, preferably in the form of the glycerine of carbolic acid of the pharmacopœia. This is "introduced by an ordinary stilette, armed with a piece of absorbent cotton saturated in the application, and passed through the dilator, so as to avoid any of the acid being brushed off in the canal before it reaches the fundus vesicæ, where it should be retained a couple of minutes until every part of the vesical wall contracts firmly upon it." The urethral canal should then be similarly treated. Pain may be relieved by cocaine. The author says that two or three applications, at intervals of a week, will usually cure the most aggravated cases. By this means the severe operation of Emmet, with its subsequent discomforts, is avoided.

[2] Brit. Med. Jour., March 2, 1889.

ACUTE MANIA AND MELANCHOLIA AS SEQUELÆ OF GYNECOLOGICAL OPERATIONS.

Dr. T. G. Thomas,[3] in this paper, places on record what he considers a "rather remarkable experience" as to the occurrence of acute mania and melancholia as sequelæ of gynecological operations. He, in the outset, distinctly states that he does not regard these states as complications, or necessarily as results, of the operative procedure, but merely as sequels which may or may not be dependent upon it; nor does he wish to be understood as claiming that gynecological operations are especially liable to such sequences.

After stating what he understands by acute mania and acute melancholia, he relates six illustrative cases,

[3] Med. News, April 13, 1889.

four of which belong to the first class, and two to the second. In four of them, there was evidence of eccentricity even before operation, though in none of them could Dr. Thomas discover evidences of hereditary tendency to insanity. Four of the six cases died, one completely recovered, and one was still in progress at the time of the report.

In current medical literature the author has succeeded in finding the account of twenty other cases of acute mental aberration following upon the performance of gynecological operations. The questions which are suggested by these facts are briefly: (1) Were these the direct result of the operations, or merely coincident states? (2) Is the proportion larger than would naturally occur in so many operations? (3) If the mania is a consequence how is it to be avoided? and (4) Are gynecological operations more likely than other surgical procedures to disturb the condition of the mind?

ON THE INDICATIONS FOR OPERATIVE TREATMENT OF DISEASED TUBES.

The author, W. A. Freund,[4] refers to the fact, that neither the knowledge of the anatomical conditions nor of clinical facts has kept pace with the skill in operating in cases of chronic inflammation of the pelvic organs. To throw some light on this obscurity is the object of this lecture.

Freund refers the variations in the forms of tubal disease, as well as the tubes themselves, to pre-existing anatomical peculiarities. As a result of careful investigation, he has enlarged our knowledge of the growth and changes in the shape of the tubes. As soon as the uterus is formed in the embryo, the tubes begin to twist spirally (from the uterine end laterally), like a corkscrew, until in the thirty-second week of intra-uterine life, they have reached their limit, and show usually six and a half distinct turns. The turn nearest the uterus is sharply defined, then follow two less marked, then three to four and a half like the first. As a result of too great a twist, irregularities may occur, and even sharp bends. From the thirty-second week, an unfolding of the spirals occurs, beginning at the median line and proceeding laterally. At birth, the portion of the tube near the uterus is only slightly wavy, the lateral curves well-marked. From birth on, the tube becomes straighter, until at puberty only the last curve, that near the pavilion, remains. This development makes the tube a patulous canal fitted for its function. If, however, this physiological development is interfered with at any point, pathological conditions result. It is rare that the tubes keep the form which corresponds to the new-born infant up to the time of completed growth. More commonly they are arrested at some stage of their growth, hence do not correspond to the age of the girl. It is rare that loops occur, and the tubes are usually alike on both sides. These grades of arrested development may exist with perfect integrity of the surroundings, and are to be clearly differentiated from the tubes bent by cicatricial bands. In these latter the canal can be with difficulty, or not at all sounded; it is frequently bent, narrowed or obstructed, and thin-wall cysts may occur in parts which are cut off. The ovum cannot freely pass through such a tube, hence danger of tubal pregnancy. Normal and abnormal secretions can be discharged with difficulty, or not at all. Such tumors of the tubes show the well-known sausage-like, irregular contours which correspond to the curves which have persisted. It is different with well-developed tubes. Here pregnancy can reach a much higher grade of development, even its normal end; retention of secretions form simple, oval, smooth sacks, sometimes of great size.

The clinical aspect of diseases of the tubes is made more intelligible by the light thrown on the anatomical relations. Well-marked lack of development of the tubes is an accompaniment of an infantile condition of the genital organs, even of the whole organization. Freund sketches the varying clinical features of the diseases of the tubes in well-developed and undeveloped women, and gives clear indications for the diagnosis of these affections.

There is also a difference in the prognosis. In affections of the abnormally developed tubes, it is materially worse than in diseases of normal tubes. In the latter, the treatment can usually be conservative; while in the former, extirpation of the diseased organs is often the only resource.

[4] Sammlung Klinische Vorträge, No. 323.

LAPAROTOMY REPEATED ON THE SAME PATIENT.

Dr. A. Martin[5] gives his experience in the repetition of laparotomy on the same person. He does not include those cases where, on account of some disturbance a short time after the operation, it became necessary to reopen the abdomen. In all there were twenty-four cases, ten of which were for trouble with the remaining ovary after one had been extirpated. These began two to nine years after the first operation. Seven times affections of the tube gave occasion for the second operation: these were partly cases which had become affected with gonorrhœa after the first operation. A third series embraced four myomata, which were not present at the first operation, but had developed rapidly. And, finally, there were three cases, two of which were in a certain sense connected with the first operation (fistulous track in the abdominal wound, ileus); and the third was for an extraperitoneal hæmatoma.

As regards the indications for and technique of such repeated laparotomies, the author advises against being led by the possibility of the necessity of a second operation to remove unnecessarily the other ovary, but to keep as much as possible; and the same with regard to the tubes, as long as they are pervious. On account of the frequency of adhesions to the old scar, he always makes the new incision at the side of the old cicatrix; and he raises the question how such adhesions are to be avoided, without, however, giving any definite rules.

PERMANGANATE OF POTASH IN AMENORRHŒA AND DYSMENORRHŒA.

Dr. Lwow[6] gives, in this article, his experience in the use of this drug. He divides the one hundred and eighty-seven cases into five groups. (1) Thirty-two cases of young, in general healthy, somewhat chlorotic, girls who complained of scanty and excessively painful menstruation. All were quickly cured by permanganate of potash, four to six grains a day, with extract of pulsatilla, taken a short time before the period. (2) Seventeen cases of women with superinvolution of the uterus following confinement, or with atrophy of uterus and ovaries. In the majority of these cases

[5] Zeit. für Geb. und Gyn., Bd. 15, Heft 1.
[6] Therapeutische Monatshefte, February, 1889.

about two years had elapsed since the last birth. The potash in the same dose, but given continuously for from three to six months, started the menstrual flow in from four to six weeks, which, with continuance in the use of the drug, took on its regular type. (3) Sixty-two cases of tardy involution of the puerperal uterus in connection with old inflammatory processes of the uterus and its neighborhood, menstruation rather scanty and painful. The results here were satisfactory, though in some cases there was no success, such cases being those in which the puerperal affection had left permanent changes. (4) Sixty-five cases of blenorrhœa of the vagina and uterus. Here the permanganate of potash had no result, in spite of its long-continued use. (5) Eleven cases of women with whom the menopause had begun too early, menstruation ceasing between thirty-five and forty. In these cases also the drug had no effect.

EXPERIMENTAL RESEARCHES ON THE CHANGES IN OVARIES AND TUBES OF RABBITS AFTER TOTAL EXTIRPATION OF THE UTERUS.

Dr. Grammatikati,[7] in view of the frequency of the operation of total extirpation of the uterus, has attempted by means of experiments on rabbits to determine the fate of the ovaries. For this purpose he removed, in some cases, the whole uterus; in others, the uterus and tubes; in still others, one horn, with or without the corresponding tube. In all cases he removed one ovary, in order to compare it with the other when that should be examined later.

He found as a result of these experiments, that, after the extirpation of the uterus, the ovaries continue to be active. The process of the ripening and the bursting of the Graafian follicles, as well as the formation of false corpora lutea, goes on without change.

He found the same to be true after both uterus and tubes had been removed.

That the same is true in women he considers probable from clinical observations. Young women on whom these operations have been performed before the change of life, show a variety of reflex symptoms, such as pain, nausea, vomiting, neuralgias, etc., which often assume a periodicity, and which may be explained by a persistence of the functional activity of the ovaries. This is not true of women operated on after the menopause.

Dr. Grammatikati had an opportunity to examine the ovaries of a woman whose uterus had been removed three years before, and found in them all the stages of development of the Graafian follicles and fully developed corpora lutea, with no sign of atrophy of the ovarian tissue.

— Dr. Henry M. Hurd, now superintendent of the State Hospital for the Insane at Pontiac, Mich., in the neighborhood of Detroit, has been appointed superintendent of the Johns Hopkins Hospital. *Science* says of him that his life has been devoted to hospital service, and he has acquired distinction as an administrator, and also as a writer. He was graduated in arts and in medicine at the University of Michigan, and has twice been called by his *alma mater* to a professorship of medicine. He has already visited Baltimore, and will permanently assume his new responsibilities on the first of August next.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

F. B. HARRINGTON, M.D., SECRETARY.

MEETING of April 8, 1889. DR. W. L. RICHARDSON, President, in the chair.

DR. G. L. WALTON read a paper entitled

LATENCY OF ATAXIC SYMPTOMS IN CASES OF OPTIC ATROPHY.[1]

DR. J. J. PUTNAM said: I have little to add to what Dr. Walton has said. This group of cases represents a distinct type of the disease. I remember a similar case referred to me by Dr. Jeffries, where the eyesight was suffering greatly, and where we could discover no other evidence of locomotor ataxia. The first signs of this disease may show themselves, sometimes in one part and sometimes another, of the central and peripheral nervous system. A recent theory is that it is of cerebral rather than of spinal or peripheral origin. I should like to ask Dr. Walton if he believes that iodide of potassium could hasten the optic atrophy.

DR. HAY inquired into the relation between the locomotor ataxia and the atrophy of the capillaries of the disc.

DR. WADSWORTH: The cases of locomotor ataxia which have come under my observation have been, naturally, chiefly those in which sight has been affected or the ocular muscles paralyzed. As regards the sequence of symptoms, I have seen optic atrophy precede the other symptoms by many years, and I have known it to come on several years after the lightning pains, at least, had been present. I have also seen the knee-jerk present where there was well-marked ataxia and pains, as well as pronounced optic atrophy. One fact which has struck me is the comparative frequency with which intelligent patients speak of the failure of sight having been first noticed in dim light. As to the field of vision, to which Dr. Putnam referred, in my experience it presents great variations: it is often much contracted, but, on the other hand, with well-marked atrophy and decrease of central vision, it may not be at all reduced in size.

DR. MILES STANDISH: Cases of locomotor ataxia with an early appearance of optic atrophy are common, the consequent impairment of vision being the only symptom noticed by the patient in very many cases. As a rule, where the optic atrophy is such an early symptom, the ataxic symptoms progress slowly, and may even stand still for very considerable periods, as five, ten, or fifteen years. I believe that the use of iodide of potassium will retard the progress of the optic atrophy and consequent loss of vision. Two cases which I have been watching for a long time, and in whom the locomotor ataxia has not notably advanced during that period, have gradually developed a diplopia, which is, however, not constant in amount, but notably increased by fatigue. By the use of prisms, it has been possible for them to attend to business.

DR. HOOPER asked about the value of Charcot's method of suspension for the treatment of locomotor ataxia.

DR. WALTON, in closing the discussion, stated that his own experience with Charcot's method was limited

[1] See page 108 of Journal.

to one case, which he had seen in consultation with Dr. Knapp. Dr. Knapp had suspended the patient a few times only at the City Hospital, with, so far, negative results. The ataxia in this case was well advanced and it was not improbable that the effort of getting to the hospital tended to counteract the benefit of the treatment. With regard to the question of deafness in locomotor ataxia, Dr. Walton had investigated upward of forty cases, in many of whom deafness existed; but in none had there been deafness by bone conduction or loss of special tones, the deafness in every case being due to extraneous cause (cerumen, chronic catarrh of the middle ear, and in one case purulent inflammation with perforation of the drum-head). He had, however, found vertigo in a large number, with tendency to fall in certain directions, this symptom appearing and disappearing in some cases, like diplopia, and not sufficiently accounted for by either ocular or aural trouble. He had drawn the conclusion that the aural fibres of the eighth nerve were not specially liable to be attacked by the disease, but that it was not improbable that the fibres which preside over equilibrium, and which pursue a different course centrally, were subject to the sclerotic process. As to the question of iodide of potassium hastening optic atrophy, he was sceptical. The atrophy was liable in any case to advance with great rapidity, and he would hesitate in a given case to attribute the advance to the iodide. In fact, as Dr. Standish had suggested, its influence was as likely to be beneficial as the reverse. In the case quoted, the patient had become worse under nitrate of silver, and improved again under the iodide.

DR. JOHN HOMANS, 2nd, read a paper entitled

DEMENTIA FOLLOWING ETHER.[2]

DR. EDWARD COWLES said: Persons predisposed to insanity may in rare cases, have mania after anæsthetics. "It is the fact of the temporary disturbance of function, and not the means by which this is produced, which is of most importance" (Savage). The question as to the propriety of using anæsthetics should include neurotic and hereditary conditions.

Dr. Cowles related the history of a woman who had been brought to Somerville after having an operation for lacerated perinæum two weeks previously. She was "somewhat demented, confused and incoherent; had hallucinations of sight and hearing." Three weeks later she was discharged from the asylum, went home and continued well.

DR. H. R. STEDMAN said that the cases were striking ones, and seemed at first glance genuine cases of cause and effect. He was inclined to think this only partially true, however, as toxic insanity occurs (almost invariably) only after prolonged and excessive use of the poisonous agent, as is the case with alcohol and lead which are also far less evanescent in effects than ether. Moreover, genuine toxic insanity is of a different and more uniform type than that manifested in the cases reported. He thought, nevertheless, that the ether might hold a place as a factor, in the causation, together with the patient's evident predisposition to mental disorder, and the shock, so to speak, of the operation.

DR. J. J. PUTNAM said: I have not seen mental diseases after ether, but recall one case in which tinnitus aurium began immediately after etherization for examination, without operation, and has persisted for two years or more. Later, the patient became suddenly deaf in one ear. She was a nervous woman, and the intensity of the tinnitus and deafness can be made to improve for a time by strong impressions, though they never disappear entirely.

DR. STANDISH said that cases at the Eye and Ear Infirmary, after the operation for cataract, both after ether and after cocaine, sometimes wander about on the third or fourth day as if suffering from dementia. It is sometimes attributed to the atropine which has been used.

DR. C. M. GREEN: I recall the case of a woman operated upon for prolapse of the uterus. The patient on the fourth and fifth day got out of bed, ran about the room, and gave much trouble. I thought at the time that the mental aberration was due to the shock of the operation. It may have been due to the anæsthetic. I learned one fact from this occurrence; namely, that the stitches in a perinæum do not necessarily suffer because of movement on the patient's part. In this case there was no ill effect from the patient's being about on her feet, the stitches holding perfectly.

DR. JOHN HOMANS showed a

SLOUGHING VERMIFORM APPENDIX

from a case of appenditis, and referred to six other cases which he had recently operated upon.

AMERICAN OTOLOGICAL SOCIETY.

TWENTY-SECOND Annual Meeting, held at the Pequot House, New London, Conn., July 16, 1889.

The Society was called to order by the President, DR. J. S. PROUT, of Brooklyn.

The first paper read was entitled

INFLAMMATION OF THE TYMPANIC ATTIC AND PERFORATION IN SHRAPNELL'S MEMBRANE,

by DR. B. ALEXANDER RANDALL, Philadelphia.

The author reported 20 cases, 15 of which had been seen in the past six months, and urged that the condition was not a rarity. It often coexists with one or more perforations of the other parts of the drum-head. If sought and recognized early, it is a less tedious and serious matter than these attic inflammations are generally considered to be. He cited some 120 cases reported by several observers among 10,000 patients, and while he had seen a still larger proportion, accepted this as the average. Passing over the treatment as having been already thoroughly discussed, he turned to the question of causation, and cited the views of Walb, that infection from without through a "foramen Ravinii," was the starting-point. Contesting the view as to any colotomatous opening in the flaccid membrane as wholly negatived by modern embryologists, he urged that the individual variations in the septa in the attic predisposed some cases to localized inflammation, and led to perforation at this point; and that these cases, neglected or recurrent, formed the group from which the usual obstinate cases were derived. He therefore advocated scrupulous search in all cases for disease in this locality, as promising to nip in the bud what might later become disease notoriously difficult to control. The paper was illustrated by drawings and photographs of specimens.

DISCUSSION.

DR. S. O. RICHEY, Washington: I have frequently

[2] See page 110 of the Journal.

seen perforations elsewhere associated with perforations in Shrapnell's membrane. The presence of perforation in other parts of the drum membrane does not exclude its presence in Shrapnell's membrane.

Dr. J. O. Tansley, New York: I have never met with perforations of that part of the drum to which the doctor refers, associated with perforation in other parts of the drum. A singular thing is that we so rarely get the perforation whistle.

Dr. S. O. Richey, Washington: I do not think that perforations of Shrapnell's membrane are so common as has been stated. My experience with the absence of perforation whistle corresponds with that of others. I have had cases in which perforations in other parts of the drum healed, but the perforation in Shrapnell's membrane persisted. In treating these cases, besides using measures through the external auditory meatus, I have employed injections through the catheter, consisting of nitrate of silver one part, boric-acid ten parts, glycerine twenty parts, and water five hundred parts.

Dr. Gorham Bacon, New York: I have not observed this condition so frequently as Dr. Randall. It is often difficult to see these perforations. In treatment, I have generally used Blake's intra-tympanic syringe. By persistant syringing and the use of astringents, cicatrization is often produced. These cases are, however, very tedious.

Dr. J. A. Andrews, New York: In treating these cases in which there is purulent inflammation of the attic, with a large hole in Shrapnell's membrane, after injecting the cavity, I suck out the fluid by means of this instrument, consisting of a delicate metal tube with a curved extremity, to which is attached a rubber tube. I use simply a boric-acid solution. After sucking out the fluid, I dry it with cotton wrapped on a probe. I then blow in a fine cloud of boric-acid.

Dr. Herman Knapp, New York: There is a capital difference between perforations in the upper and those in the lower part of the drum membrane. Those in the lower part may close in a few days, while in the upper part they may continue for months or years. I think this is due to difference in anatomical structure. The lower portion is a specific tissue with little association with periosteum, while the upper part is a duplicature of periosteum and skin. When the latter part is affected the process extends to the periosteum leading to caries and necrosis of the bone.

THREE DEATHS FOLLOWING SUPPURATIVE OTITIS, WITH TWO AUTOPSIES,

by Dr. F. M. Wilson, Bridgeport, Conn.

Cases in which death follows a first attack are so rare that it was thought of value to report these cases. The first patient was forty years old, and for two weeks before coming under observation had had pain in both ears. February 27, 1888, the pain in the left ear became very intense. March 1st, he became partially unconscious, and remained so with occasional convulsive movement until March 6th, when he died. The mastoid was drilled half an inch, but no pus found. No autopsy was made.

The second case, a male aged twenty-three years, was attacked with sub-acute otitis. March 11th, symptoms of meningitis appeared, with high temperature, and he died March 27th. At the autopsy one-third of the base of the cerebrum was involved in the purulent process, which extended up under the frontal convolutions; there was about half an ounce of turbid fluid between the dura mater and inner meninges. There was pus in the labyrinth and in the tympanic cavity.

The third case was that of a boy aged ten years, who was attacked with suppurative otitis, September 5th, and died about ten days later. At the autopsy the meninges were found normal, but an abscess containing two drachms of fluid was found in the cerebellum.

Dr. Wilson also presented a

MASTOID DRILL,

provided with a guard which could be set at any desired point, regulating the distance to which the drill entered. The edges of the drill are sharp, so that the opening can be enlarged horizontally to any desired extent.

DISCUSSION.

Dr. Gorham Bacon, New York: It seems to me that in these cases where we do not find any collection of pus in the mastoid cells, we are justified in investigating the condition of the brain.

Dr. J. O. Tansley, New York: I have had several of these cases, and have without success sought for some means by which we could differentiate between those cases in which there was meningitis and those in which there was abscess. In one case, Dr. Seguin made a diagnosis of abscess, based upon conjugate deviation of the eyes. Subsequent autopsy showed the correctness of this diagnosis. In another case I suspected abscess. Dr. Weir opened the mastoid, but found no pus. He also exposed the cerebrum, and two days later the cerebellum, but found no pus. The patient died of suppurative meningitis.

Dr. S. D. Risley, Philadelphia: It seems to me, that in the differential diagnosis, attention to the temperature in connection with symptoms of pressure, is of great importance. In meningitis the temperature from the outset will be higher than in abscess, and the symptoms of pressure come on later.

Dr. J. A. Andrews, New York: In the past year I have made a number of autopsies in cases of brain abscess. Brain abscess may continue for a considerable time without any very positive symptoms, but where there is meningitis or phlebitis, especially phlebitis, there is usually a sudden rise of temperature with chills.

Dr. Oren D. Pomeroy, New York: In a case of brain abscess secondary to tympanic disease, the only marked symptom was a sudden rise of temperature, sometimes going up in half an hour from normal to 107°. Intelligence was unaffected until the last. The man gradually improved, but died suddenly. The autopsy showed a large abscess of the brain covering the petrous portion of the temporal bone.

Dr. Arthur Mathewson, Brooklyn: It is often difficult to make a diagnosis between abscess and meningitis, and in fact many are mixed cases. In meningitis the pains are more marked than in abscess. In meningitis, there is more likely to be optic neuritis; while in brain abscess, I have noted a peculiar dark appearance about the retinal veins.

Dr. Samuel Theobald, Baltimore: The treatment of the preliminary stage of these cases is important. It seems to me that a great deal might be done to prevent the occurrence of the conditions referred to. I have found benefit from local applications, especially atropia and cocaine and morphia and cocaine. If the

bowels were constipated, I should use a calomel cathartic. If there should be symptoms of cerebral implication, I should administer mercury in some form to secure its constitutional effect.

DR. E. FRIDENBERG, New York: During the past eighteen months, I have made autopsies on two patients dead from cerebral abscess. In one case suppuration had lasted a year, but there had been no symptoms until a week before death, except irritability of temper. There was some odor, but very slight discharge from the ear. A week before death the patient developed pain in the ear, slight tenderness over the mastoid followed by fever and symptoms of brain pressure. A small abscess was found in the tempero-sphenoidal lobe. The roof of the tympanum was carious and the meninges strongly adherent.

In the second case the patient had had suppuration for years. Two months before death headache occurred, which was relieved by treatment. It recurred, with fever. There was some pain on pressure over the mastoid process. The symptoms again disappeared under treatment. Three weeks later he returned with similar symptoms. The next morning vomiting occurred, and that evening he died. An abscess containing two ounces of pus was found in the tempero-sphenoidal lobe.

DR. T. Y. SUTPHEN, Newark: These cases of brain trouble almost invariably follow the arrest of the flow of pus. We should look upon the cases as instances of local trouble, and should treat the middle ear by fomentations, and perhaps by poultices, to bring about free discharge of pus.

DR. R. A. REEVE, Toronto, Can.: In one case of death following acute suppurative otitis, there was the most profuse purulent discharge that I have ever seen, and it continued from beginning to end.

DR. B. ALEXANDER RANDALL, Philadelphia: A case of cerebral abscess occurred in my practice last year, in a boy, the subject of scrofulous disease of the elbow and other joints. I found both ears discharging with caries of the auditory meatus on both sides. On the left, all the mastoid tissues were involved. Under treatment the right side rapidly improved, and on the left side there was also improvement. The case was then transferred to my surgical colleague. Six weeks later the ears were still in good condition, but the patient was gradually failing from the constitutional trouble. An hour before death there was suddenly a discharge of at least two ounces of fetid pus from the ear. There was no meningitis, but a large abscess cavity was found in the spheno-temporal lobe, and one half-inch from the tympanum and connected with it by a sinus.

In cases where it is thought justifiable to perform exploratory trephining of the brain, an admirable and safe point is one and one-fourth inches behind, and an equal distance above, the upper posterior margin of the osseous meatus. This avoids the major blood-vessels, and it would be possible to reach the cerebellum through it.

COMPLETE CLOSURE OF BOTH EXTERNAL AUDITORY CANALS BY BONE, IN A PATIENT HAVING GOOD HEARING POWER, WITH A PREVIOUS HISTORY OF CHRONIC SUPPURATIVE OTITIS MEDIA,

by DR. E. E. HOLT, Portland, Me.

T. M., age eighteen years, was seen in April, 1889, for an affection of the eye. It was incidentally learned that he had had abscesses in both ears when seven years old, and the ears discharged more or less for six years, but stopped entirely five years since. Examination showed the canals of both ears of about half the usual length, and occupied by a continuation of the skin of the meatus, with no appearance of the membrana tympani. There was complete closure of the canal by what appeared to be bone by all the tests employed.

The hearing power for the voice was good. The stop-watch was heard only when close to the ear; the tuning-fork was heard about ninety seconds both by bone and ærial conduction. König's rod of thirty thousand vibrations per second was heard by both ears. He heard less distinctly when both ears were closed by pressure on each tragus. Shutting the mouth and closing the nostrils did not seem to effect the hearing power much if at all. Cases with closure of one meatus with the skin of the canal continuous over the obstruction have been observed, but the hearing power is very defective. Cases in which there is a small opening between the exostosis and the walls of the meatus are not uncommon.

DISCUSSION.

DR. SAMUEL THEOBALD, Baltimore: Four or five years ago I reported a case very similar to the one described. The newly formed membrane was, however, nearer the orifice. The hearing power was good.

DR. B. ALEXANDER RANDALL, Philadelphia: I have had one case in which one ear was obstructed by a bony mass. There was no evidence of exostosis. The hearing was, however, defective.

OTITIS MEDIA CATARRHALIS ACUTA, ACCOMPANIED WITH FACIAL PARALYSIS AND IMPAIRMENT OF ACCOMMODATION OF THE EYE OF THE AFFECTED SIDE,

by DR. E. E. HOLT, Portland, Me.

Judging from statistics, one would be led to believe that paralysis of the facial nerve in connection with acute catarrhal inflammation of the middle ear was not a common complication. In many cases the pain having been slight, and having passed off and the paralysis having come on, the patient's attention is directed to this and he seeks advice for the latter affection, and the cause of the paralysis is recorded, "a cold," or "rheumatic."

F. L., age twenty-four, seen May 19, 1889. Seven days before took cold, and right ear began to pain that night. This pain continued three days, when it subsided; and on the fourth day he was unable to use his lips properly. Examination showed all the characteristics of facial paralysis. Testing the eyes, there was found paralysis of accommodation of the right eye. This the author knew to be a fact, because he had previously had the patient under his care and recorded the test of his eyes, and also by the fact, that, since the improvement of the paralysis of the face, the paralysis of accommodation has disappeared.

THE PHYSIOLOGY OF THE INTRO-TYMPANIC MUSCLES.

by DR. S. O. RICHEY, Washington, D. C.

The paper was the elaboration of a suggestion made by the writer in the discussion of a paper read by him at the Congress of American Physicians and Surgeons, in 1888. If the membrana tympani in pur-

pose protects the aural tissues lying interior to it, these muscles, being appendages to the membrane, are designed to assist the purposes of the membrane, which they do in part, by protecting it from injury by the impact upon it of sound impulses violent enough to rupture an inflexible membrane firmly attached and having such a plane as to expose it to the fullest force of the concussion. The membrana tympani fulfils one of these conditions; it is firmly attached. Toynbee and Henle were quoted as having many years ago expressed a somewhat similar view as to the action of the tympanic muscles, and it was stated that no reference to this subject by later writers was found. The shape and other peculiarities of the auditory meatus; the elasticity and capacity for motion of the drum membrane, and its oblique position with relation to the meatus; the co-ordination between the palatal and the intra-tympanic muscles, converting the tympanic cavity into an air-cushion, all indicate a similar purpose on the part of nature to guard the membrana tympani immediately, and the labyrinth mediately from violence.

EVENING SESSION.

DR. GORHAM BACON, of New York, exhibited photographs of the ear, and read a paper on

CYSTS OF THE AURICLE.

Of late a number of cases of so-called cysts of the auricle have been reported. Not one of them, however, seems to represent a genuine cystic tumor such as is found in other parts of the body. They all were situated on the anterior surface of the pinna, and were of rapid development. They either were the results of traumatism and contained a sanguinolent fluid, or they developed without known cause. Mild inflammatory symptoms were present in all. The development within two or three weeks, in almost all cases, distinguishes them clearly from the slow and absolutely non-inflammatory development of true cystic tumors. All got well either by spontaneous absorption or by incision. The speaker had seen at least half a dozen of these cyst-like sub-perichondrial swellings of the auricle. He considered them to be mild cases of perichondritis, for those mild cases of circumscribed perichondritis may, instead of getting well, remain in this condition for a time, and then develop into the full picture of a diffuse perichondritis. He reported such a case.

DR. KNAPP also described a case of genuine cyst of the auricle, occurring in a girl nineteen years of age. The growth was double the size of a large filbert, distinctly cystic, and had developed without known cause and without any inflammatory symptoms. The cyst was removed by operation, without rupture, and was exhibited. These tumors are not frequent in the auricle, but they cannot be so rare as we might infer from otological literature.

EPITHELIOMA OF THE MIDDLE EAR.

by DR. W. H. CARMALT, New Haven.

The patient, a robust man aged forty-seven years, was first seen in June, 1888, on account of suppurating ear (left), which had existed forty-two years, and had followed measles. The ear had given him no inconvenience, with the exception of the discharge, until a few weeks before he came under observation. He then began to have pain in and around the ear and the discharge was exceedingly offensive. The canal was blocked by a ragged but firm excrescence, very sensitive to touch. There was slight tenderness but no swelling or pitting over the mastoid. The pain radiated through the side of the head and interfered with sleeping. At the second visit, the left side of the face was completely paralyzed. The case was regarded as one of epithelioma of the skin of the canal. The patient was seen by another gentleman who thought the trouble might be a carious antrum. An attempt was therefore made to open the antrum, but the bone around it was so sclerosed that the cavity was practically obliterated. There was nothing of the nature of an abscess in the mastoid. The incision was then prolonged through the soft parts and into the external auditory canal. What polypoids could be reached were removed, and a drainage tube inserted. The mass removed proved to be carcinomatous. In the course of a few weeks the ear again became blocked up, and the skin became involved. With the object of alleviating some of the distressing accompaniments of the condition, another attempt was made to clear it out. By chiselling away the bone posteriorly, free access to the ear cavity was obtained, and the bone scraped apparently clean. No auditory apparatus was seen, simply a mass of carcinomatous tissue. The cavity was washed with a solution of resorcin, and for a time the wound did well, but subsequently the disease reappeared. The discharges became again offensive and the patient exhausted, and he finally bled to death without the condition being detected, probably from erosion of the lateral sinus. No autopsy was permitted.

DR. B. ALEX. RANDALL exhibited a series of

PHOTOGRAPHS,

and made some remarks on the use of photographs and of the lantern in treating otology.

Dr. Randall also reported five cases of

SUPERNUMERARY AURICLE,

four of the right ear, one of the left ear.

Dr. T. Y. SUTPHEN, of Newark, exhibited a mumified pea, which he had removed from the auditory canal, where it had lain for nineteen years. The patient had been deaf in that ear since childhood. He heard the watch at one inch; after removal of the foreign body, the hearing was almost normal.

DR. B. ALEXANDER RANDALL made some remarks upon the

ANATOMY OF THE DRUM MEMBRANE.

A paper entitled

TWO NOTEWORTHY CASES OF TRAUMATIC RUPTURE OF THE MEMBRANA TYMPANI

was presented by DR. HUNTINGTON RICHARDS, New York.

CASE I, seen May 7th, a woman aged thirty, two days before had received a box on the left ear. The symptoms were vertigo, tinnitus and marked deafness. There had been no bleeding or other discharge. There were some evidence of pre-existing tympanic catarrh in that it was somewhat depressed and moderately atrophic; save for pronounced congestion of the manubrial vessels, and a narrow red line along the border of the opening, it was not congested. The exposed inner wall of the tympanum was likewise pallid, secreting only sufficient mucus to give its surface a glistening appearance. The patient was directed to let

the ear alone, and a small loose cotton obturator was placed in the auditory meatus.

CASE II, a woman aged twenty-three, came under observation, May 22d. There was no discharge or bleeding. There was no congestion of the membrane or of the tympanic wall. The patient had complained of aural symptoms for several weeks. On May 21st, she consulted a physician, who introduced a cotton-covered probe. This made her so dizzy that she had to lie down immediately, and within two hours she discovered that she was very deaf. The treatment was negative, and up to May 31st, no change had occurred. The edges of the opening were then stimulated with nitrate of silver solution and a small quantity of boric acid was insufflated. Examination made a few days later showed that the opening had healed, with the exception of a small part. The patient then passed from observation.

EXECUTIVE SESSION.

Officers for ensuing year: *President*, Dr. Oren D. Pomeroy, New York; *Vice-President*, Dr. Gorham Bacon, New York; *Secretary and Treasurer*, Dr. J. J. B. Vermyne, New Bedford, Mass.; *Member of Executive Committee of Congress of American Physicians and Surgeons*, Dr. W. H. Carmalt, New Haven; *Alternate*, Dr. F. B. Loring, Washington, D. C.; *Committee on Membership*, Drs. Arthur Mathewson, Samuel Theobald, and S. D. Risley; *Committee on Publication*, Drs. J. J. B. Vermyne, C. J. Blake and J. Orne Green.

A committee consisting of Drs. S. C. Ayres and Wm. W. Seely, was appointed to prepare a minute on the death of Honorary Member, Dr. E. Williams, of Cincinnati.

The following were elected to membership: Dr. Harlan P. Allen, Columbus, Ohio; Dr. Ralph M. Seiss, Philadelphia, Pa.; Dr. David Harrower, Jr., Worcester, Mass.; Dr. Robert Barclay, St. Louis, Mo.; Dr. Neil P. Hepburn, New York, N. Y.

Recent Literature.

Synopsis of Human Anatomy, being a Complete Compend of Anatomy, including the Anatomy of the Viscera, and Numerous Tables. By JAMES K. YOUNG, M.D., Instructor in Orthopædic Surgery and Assistant Demonstrator of Surgery in the University of Pennsylvania. Philadelphia and London: F. A. Davis, Publisher, 1889. Physicians' and Surgeons' Ready Reference Series.

In saying that this book is good of its kind, we mean to pay it a very relative and modified compliment; for the kind is detestable, and this has merely the merit of being better than most of its class. Intrinsically considered it is very poor. Judging from the preface, the author apparently thinks it a sufficient text-book. We cannot congratulate him on his "well-selected wood-cuts," nor agree with him that "sufficient descriptive matter has been added to render it valuable to the busy practitioner." Some of the tables and diagrams are useful, but neither the text nor the illustrations are satisfactory. We see no reason to suppose that this will take the place of any good work on anatomy. A man who cannot afford to buy one of the standard text-books had better not study medicine.

T. D.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 1, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

THE ALLEGED SPONTANEOUS COMBUSTION OF THE HUMAN BODY.

WHEN "Bleak House" appeared, in 1853, novel-readers were treated to a new sensation in the way of a death-scene, when Krook was taken off the stage by spontaneous combustion, "of all the deaths that can be died." The public shuddered and medical readers smiled. The subject was then to most physicians, as it is now, well inside the border of medical mythology. Medico-legal authorities naturally reacted from the often manifestly unreliable cases which were at first reported, and with some leading medical journals, discredited the whole thing. The *Lancet*, in 1875, spoke of "the few apocryphal cases of it," and the *Medical Times and Gazette*, in 1863, editorially classed all the reported cases somewhat contemptuously under "popular medical errors." The writer put into the same category of humbugs with it such subjects as prenatal maternal impressions on the fœtus, "vegetarianism and teetotalism."

Within the past year or two several cases have been put on record, which, with the list previously accumulated, serve to establish pretty clearly the fact of an occasional abnormally increased combustibility of the human body, which, it should be observed, does not necessarily imply ignitability, or true spontaneous combustion.

For instance, Dr. Booth's case, which is reported with a photograph of the nearly consumed remains,[1] is of a pensioner, aged sixty-five, of very intemperate habits, who climbed into a hay-loft while drunk, at nine P.M. Neighbors saw by a skylight, a light struck, which after a while was put out. At eight the next morning, the body, with all its soft parts consumed, was seen lying over a hole in the floor which had nearly burned through, but had one or two joists that kept the body from falling through. The chance of the application of fire to the man's clothes is here distinctly stated; and the combustion, remarkable as it was, is not shown to have been spontaneous.

[1] British Medical Journal, vol. i, 1888, p. 841.

Again, Middlekamp[2] reported a similar case of nearly complete combustion, where the victim, a man of sixty-six and a drunkard of twenty years' standing, fired a gun at his own breast, with a ramrod. Here the heat was so intense as to melt the ramrod and a metal buckle. The body was consumed entirely, except the lower part of the legs, the head and the arms.

In the *Therapeutic Gazette* of the current year, two more such instances are reported. Of these, Dr. Clendenin's[3] was an old Irish woman, addicted to the excessive use of whiskey of which she had drunk a quart the day she died. She had always been the last of of the household to go to bed, and so always extinguished the tallow candle (their sole means of illumination). There was also a fire in the kitchen stove. The inner walls of the house were covered with greasy soot, and the two old men who were the only other occupants were both asphyxiated. A hole was found burned through the kitchen floor, about two and one-half by three feet square. Upon examining the opening in the floor, a mass of cinders was discovered on the ground beneath. Upon removing them the skull, the cervical, and half the dorsal vertebræ were found reduced very nearly to a cinder, also about six inches of the right femur, together with part of the ilium in about the same state as the vertebræ. The feet were found in the shoes; the left foot was reduced to a cinder, the shoe being partially calcined; the other foot and shoe were reduced to a complete cinder. On removing, the entire remains of a woman, who a few hours previous had weighed one hundred and sixty pounds, were placed in a box that would hold less than one bushel. The entire remains weighed twelve pounds. The pine joint against which the remaining cinders lay were slightly charred, but not burning when found.

To burn the human body, under ordinary circumstances, is not an easy thing. The great heat secured in crematories, and the length of time even then requisite to incinerate the body, illustrate this fact. It has been shown that the body is three-quarters water, and a great deal of combustible material is a necessary adjunct to the successful reduction of so non-inflammable a substance. What, then, is it that occasionally imparts to it so abnormal a susceptibility to flame? Here theories are at fault. We may safely say that it is *not*, as has been claimed by some, alcohol deposited in the tissues. For Liebig found that flesh saturated in that liquid would burn only until the alcohol was consumed. The hydrogen theory is also fanciful; and the best explanation, namely, an abundant deposit of fat in the cells of the body in such cases, fails to account for the fact that not all fat people are subject to this fate, but that it is only the fat, elderly *alcoholic* subjects that have been shown to manifest abnormal combustibility. Possibly the alcohol in such cases has the double effect of laying up fat and stupefying the subject so that he is unable to save himself when he does take fire.

[2] St. Louis Medical and Surgical Journal, October, 1885.
[3] Therapeutic Gazette, June 15, 1889.

One of the best recent monographs on this subject is that of Dr. F. Ogsten,[4] which details a case of his own — again, be it observed, one where the spontaneous element was wanting, or was not proved. A woman, fat, intemperate, was in front of smouldering ashes in a grate, and was almost wholly consumed, with little burning of the surrounding objects, and with nothing specially inflammable about her. Ogsten seems to have had some doubt on this subject, seven years later, in referring to the same case,[5] when he says the question is still *sub judice*; but he admits that one cannot explain the facts in this case without assuming that the body was in a condition unusually favorable for and predisposed to the feeding at its own fire.

In the monograph referred to, Ogsten collected the opinions of thirty-five authors who treated of this subject, and he thus classified them: Five were quite sceptical on the whole subject; three believed in increased combustibility only, and twenty-seven believed in spontaneous ignitability as well.

The necessarily isolated condition of all persons who perish in this way, and the commonness of fires and lights or of the means of producing them in all places, would make it extremely difficult to establish the fact of spontaneous ignitability, even did it exist. Certainly such proof has not yet been given us. The other point, that of increased combustibility, seems to have received considerable confirmation.

STENOGRAPHY AS AN ADJUNCT TO A MEDICAL EDUCATION.

SOME months ago, we directed attention editorially to the desirability of stenography as an adjunct to the study of medicine, and some of its advantages to the student and the practitioner were then mentioned. The fact was pointed out that the system of teaching in all the more advanced medical schools is now so changed that the "lectures," formerly almost the only medium of instruction, are to a great extent superseded by other and more valuable methods, in the way of accurate and visible charts, of systems of clinical and pathological investigation, in which diagrammatic and concise schematic representations of the course and direction of the disease processes replace the less satisfactory teachings of earlier days. This change in method allows the possibility of a clear and defined history on the course and tendency of the disease process, and of forming a clinical picture which shall afford to the eye a distinct representation of the case in its entirety. A clinical examination is now often augmented by means of photography. What photography is to the ordinary drawings of former days, to a considerable degree shorthand is to the ordinary means of taking notes either in the class or at the bedside.

The use of some means of correctly and quickly taking notes of cases, or other interesting records in

[4] British Foreign Medico-Chirurgical Review, vol. xlv. p. 179.
[5] Medical Times and Gazette, vol. i, 1877, p. 27.

relation to medical subjects is each year more and more urgent, and is making itself felt in every great institution of medical teaching. It is with especial pleasure that we find that some of our English brethren are of the same opinion as ourselves in this respect.

In the *British Medical Journal*, June 15, 1889, page 1372, we find some remarks based upon the report of a committee appointed to investigate and encourage the use of shorthand in relation to the study of medicine. This committee was composed of Sir Dyce Duckworth, Mr. Howard Marsh, Dr. Gowers and Dr. Coupland, men of the first eminence in the profession in England; and their report is made the object of recommendation in the remarks above alluded to. This committee propose to offer prizes to students in medicine who shall exhibit the greatest proficiency in stenographic reports of medical subjects. Such a recommendation coming from so competent a committee should at once attract renewed attention to this topic, and lead students of medicine, or those intending to become such, to seriously entertain the question of acquiring the art of rapid and correct transcription of ideas in permanent form for future reference. The ordinary notes of lectures or clinics are but the most crude and naked outline of the subjects treated, all detail and much of importance in the chief features of the case being of necessity lost from sheer inability to take down more. With a moderate amount of study and a limited expense of time, the student might be enabled to make ready and complete descriptions of all interesting subjects.

The use of stenography is by no means confined to one profession or calling, but like photography, is applicable to all the objects of observation or study coming under the notice of the student. It is especially desirable in the notes of cases in daily medical practice, by which the hard-working physician is able to readily and easily make a complete record of symptoms and signs not otherwise often recorded, an item not to be lightly estimated. In the Massachusetts Medical Society for instance, there are, we believe, but few men who are able to make accurate records of discussions or proceedings, in verbatim form. Medical stenography is unlike any other branch of this art, inasmuch as many of the terms employed are of technical character and are not comprised in any vocabulary or system of common shorthand. So that a report of a meeting or discussion made by an ordinary stenographer is apt to be very unsatisfactory. There is no difficulty other than a merely idiomatic one in the use of stenography in any special direction, and medical shorthand is fully legible and easily written by a medical man.

It is to be hoped that more attention may be directed by the younger members of the profession and by medical students to this neglected art. It is true that a motion made to the General Medical Council by Sir Dyce Duckworth, in favor of encouraging shorthand was rejected, and if the use of shorthand were necessarily to take the place of the use of brains, the objections urged by its opponents would be of much weight.

THE HEREDITY OF TUBERCULOSIS.

HUTINEL, of the *Hôpital des Enfants Malades*, has published a communication on the "Heredity of Tuberculosis," [1] of which the conclusions are as follows:

As for the direct transmission of the germ from the parents, we are warranted in affirming that communication by the father is not proved, and is very problematical; transmission by the mother may take place, but it is extremely rare.

Heredity, nevertheless, exists; for if the offspring of phthisical parents are not born tuberculous, they are *tuberculizable*; they may not, it is true, have brought with them the germ from their birth, but they have inherited a culture soil (*terrain*) favorable to its development.

In accordance with these conclusions, which are in harmony with a multitude of clinical observations, Langerhaus, who has long practiced in Madeira, has noted that among the individuals not phthisical that have come to that island for a certain number of years, only those born of tuberculous parents become infected by the numerous phthisical patients resorting to that island every year. Of every ten individuals with phthisical parentage, one died of tuberculosis, while the proportion of those becoming consumptive with no hereditary predisposition has been as one to sixty-eight.

MEDICAL NOTES.

— Apache county, Arizona, is said to be without a practising physician, though possessing a population of several thousands.

— Dr. Zweifle, of Leipzig, has recently successfully removed a cancerous uterus in the sixth month of pregnancy.

— The library of the late Dr. Jewell, of Chicago, numbering about 3,000 volumes, has been secured as the nucleus of a medical library for general use.

— The Director of the Assistance Publique has distributed among the *infirmiers* and *infirmières* of the Paris hospitals 2,000 tickets for the Paris Exhibition.

— A new hospital for women in West Philadelphia, under the care of women physicians, the second of its kind in the city, is to be opened at the northeast corner of Forty-first and Ogden Streets.

— Deutsch reports a case in which rupture of the uterus was successfully treated by laparotomy. Four years after, the patient was again pregnant, and a living child was delivered by podalic version. The placenta was adherent to the scar resulting from the previous rupture.

[1] Semaine Médicale, 1889, p. 229.

— Dr. Howard H. Kelly, of Philadelphia, associate professor of obstetrics in the University of Pennsylvania, has been appointed gynecologist to the Johns Hopkins Hospital.

— A case is given by the *Medical Press* of a man whose history is remarkable for the number of times he has obtained admission to lunatic hospitals by feigning lunacy. In the course of seven years he obtained admission to no less than twelve asylums.

— An organization has been recently established to be known as the "Military Order of Surgeons of New Jersey," the objects of which briefly stated are to promote an interest in the National Guard and to cultivate and foster the art of military surgery and sanitation.

— At the annual meeting of the directors of the St. Albans (Vt.) Hospital, held on Tuesday, July 23d, these officers were elected for the ensuing year: *President*, Hon. J. Gregory Smith; *Vice-president*, James M. Foss; *Secretary*, Charles D. Watson; *Superintendent and Treasurer*, Dr. T. R. Waugh.

— The Government of Chili has created a "Superior Council of Public Hygiene," consisting of seven members, whose duty it shall be to advise the Government in everything that relates to the public health throughout the Republic. The Council has a laboratory for chemical analysis under its control.

— The late Dr. Thayer was one of the best physicians in the country, but his skill was of no avail in the case of his wife, who kept her bed for more than two years. One day when she was the only grown person about the house, and her little boy came running in with a bad cut on his finger, bleeding profusely, with true motherly forgetfulness of self she sprang up, found bandages and dressed the wound; then sitting down to rest, she looked around. Everything seemed so pleasant, and she felt so comfortable, that she decided not to take her bed again, and she did not. She lived several years in the enjoyment of comfortable health. — *Fairfield, Me., Journal.*

— Through the efforts of Dr. Filip Trybom, the Swedish Oyster Culture Society is attempting to acclimatize the American oyster, imported from Connecticut, in several places along the coast of the province of Bohus. The young oysters seem to thrive well.

— The *Pittsburgh Medical Review* gives the following list of casualities on July 4th, in Pittsburgh: five persons drowned by the overturning of a boat; two cases of fractured skull, probably fatal; two serious gun-shot wounds; three broken legs; nine individuals severely burned by powder explosions, of whom three will lose their sight; and ten accidental fires.

— M. Brown-Séquard announces that the injection of ovarian tissue-juice into debilitated women has been tried and without bad effects. He also says that the stimulating effect of the hypodermic injections made upon himself lasted about four weeks, since which time he has returned to the previous state of weakness.

— In the cases of the State of New Hampshire *vs.* Drs. C. D. Hinman and D. D. Pennoyer of Portsmouth, the former indicted for practising dentistry and the latter medicine, without a license, the full bench of the Supreme Court has just rendered a decision quashing the indictments and declaring that the law requiring a license for the practice of medicine, surgery and dentistry is unconstitutional.

Miscellany.

MUNICH A HEALTHY CITY.

DRS. VON PETTENKOFER and von Ziemssen maintain, in a recent communication to the *Münchner Neueste Nachrichten*, that, owing to the purification of the soil by sewerage and other sanitary improvements, not only has typhoid fever lost its vitality in Munich, but certainly the conditions of the epidemical development of other diseases, as cholera, are also destroyed. Still one is not able yet to appreciate to their full extent the effects of the sanitation of the soil upon all causes of disease outside the human body. After some more decennaries shall have elapsed, we shall perhaps be able to estimate the entire gain to the general health. But even now, the reputation of the town is the best, and, in consequence of it, the influx of students, of strangers and foreigners settling there, the frequency of exhibitions, etc., is steadily increasing. It may be said, without exaggeration, that *Munich can confidently be called one of the healthiest cities in Germany.*

A REMARKABLE EPIDEMIC OF PNEUMONIA.

IN the *Maritime Medical News* for May, quoted by the *Medical Record*, there is an account of an epidemic of pneumonia in Prince Edward Island. During the months of February and March no less than five hundred and forty-six cases occurred in the practice of twenty-six practitioners, and at the date of the report the disease was still very prevalent. As there are over fifty practitioners in the island, it is computed that the total number of cases is fully upward of one thousand. As the population of the island does not exceed one hundred and fifty thousand, the number attacked is relatively very great. It appears that in the majority of cases the pneumonia was attended by acute bronchial catarrh. The catarrhal complications, which in some cases also involved the larynx and middle ear, were more frequent in children and the aged. In the five hundred and forty-six cases reported there were only forty deaths, a decidedly low mortality.

Correspondence.

THE USE OF HOT AIR IN PHTHISIS.

BOSTON, 91 Newbury St., July 24, 1889.

MR. EDITOR, — In the *Boston Medical and Surgical Journal* for July 11th, Dr. Sears, in writing on the use of hot air in phthisis, states that owing to the high temperature and consequent rarefaction of the inspired air, while the outside atmospheric pressure remains the same,

the danger of hæmorrhage is increased. This implies that the pressure in the lungs is diminished. How is this brought about? To my mind not at all. The inspired air is rarefied, but, since it is in direct connection with the atmosphere, must remain at the normal pressure. Were the air penned up, the pressure would be increased. The only way a diminution in pressure in the lungs can result, is from the friction in drawing the air through the heater, which in turn is counteracted by the tendency of the hot air to rise, as in a chimney.

The inspiration of hot air, however, does have a mechanical effect, since the air cools off in a body and becomes denser, a greater volume of air must be inspired than expired. Therefore, the normal respiration must be altered in such a way as to increase either the vigor or duration of inspiration as compared to expiration. This is quite a factor, the coefficient of expansion of air being given at .003670, the inspired air at 200° C., and the expired at 45° C., the ratio of inspired to expired volume of air would be 1.56885 to 1. The cooling, of course, produces no effect upon the weight. Of course the changes in the gases due to respiration will alter these figures, but this appears to be about the same as in ordinary respiration.

Yours very truly,

JOHN A. JEFFRIES, M.D.

[From our Special Correspondent.]

PARIS LETTER.

BIOGRAPHICAL SKETCHES OF EMINENT FRENCH CLINICIANS. PROFESSOR GERMAIN SEE.

PARIS, July 19, 1889.

MR. EDITOR,— I propose in this and subsequent letters to give a brief sketch of some of the most marked men of the profession in Paris.

Professor Germain Sée is one of the most renowned in French science. He is one of the leading therapeutists in this country; physician to the Hôtel Dieu and member of the Academy of Medicine. His clinical lectures, which are most remarkable for their lucidity, are always well attended, not only by the students of the faculty, but by foreign medical men from all parts of the world. Although a septuagenarian, he keeps himself abreast of all the modern inventions and discoveries of the day. His clinical teaching is based principally on chemical therapeutics and microbiology, without, however, neglecting the collateral sciences, such as physiology and morbid anatomy and histology. He is not very popular among his colleagues, and the elder ones have always borne him some animosity, as he attained a professorship without having passed through the grade of *agrégé*, which is obtained only by public competition. This was effected through the direct intervention of Napoleon III, and although M. Sée was not an avowed Imperialist, yet the emperor, who was rather shrewd in finding out the best men, had him attached to his person as consulting physician. It was to reward him for his services that the emperor created M. Sée, Professor of the Faculty of Medicine of Paris. This act, being contrary to the universitarian customs of the country, was the cause of his having more than one enemy in the faculty. He has since, however, proved himself qualified in every way and worthy of his position. It may be remembered that, several years before his nomination M. Germain Sée had organized, at the Hôpital Beaujon, a free course of lectures, treating of subjects little familiar to the students and practitioners who followed him in his wards. The young professor, already distinguished for his erudition, possessing a profound knowledge of several foreign languages, an expert in the technic of microscopy (a rather rare acquirement at that period), delivered lectures which were always well attended and revealed in him the highest qualities, which eventually justified the choice made by the emperor. Moreover, since he has occupied a magistral chair at the faculty, he has succeeded in conquering the sympathies of most, if not all, his colleagues. He is eloquent, which has excited the enthusiasm of the students, beside which, his teaching is original, taking in physiology to the aid of his clinical and therapeutic lectures. In a word installing science where empiricism alone reigned.

It is more especially in the art of cure that he effected great progress. As soon as a new medicament is utilized in foreign parts, particularly in Germany, M. Germain Sée who is well versed in German, seizes the discovery, makes experiments in his laboratories, attempts practical applications, and then makes known the result of his researches. The greater part of the medicaments which are now in daily use, have been vulgarized by him in France, and all that he has recommended have been accepted by the profession. His works on digitalis, the salicylate of soda, and on antipyrine, will long be consulted. More recently the learned professor published, consecutively to the discoveries of Professor Koch on tuberculosis, very interesting lectures, in which the questions of contagion, bacillosis and of treatment are elucidated with great talent. Notwithstanding his advanced age, he devotes the time allowed him after his numerous consultations, to scientific work. It is to be hoped that he will for some time be able to continue his interesting lectures at the Hôtel Dieu, and when the time comes for him to retire, the regrets, even of those who were so much opposed to him, will follow him.

Whilst writing about Professor Germain Sée, I may here refer to his most recent work on the diseases of the heart, etiologically and clinically considered, which forms part of a work written by him in conjunction with Dr. Labadie-Lagrave, under the general title of "Clinical Medicine." It comprises only the clinical study of the diseases of the heart, the second volume will take up the treatment. Like all the other grand divisions of pathology, clinical exploration and therapeutics are enriched by a certain number of important acquisitions. His tendency to microbiology is manifest in this as in all his most recent works. For instance, after having insisted on the fact that the origin of the diseases of the heart has one source, that is to say, that it proceeds from endocarditis, M. Sée has endeavored to demonstrate that endocarditis, whatever be its form, is of parasitic origin. The notion of inflammatory endocarditis becomes more and more uncertain in the face of that of the bacteric form, the demonstration of which has already been made. In a clinical point of view, the author adds, there is only one species of endocarditis which is due to the swarming of micrococci. The valvular lesions are the consequence of the morbid work effected in the tissues by the parasites, but there is not any inflammation in the proper sense of the word, as the inflammatory process is wanting. It is in reality a degenerative process. Hence M. Sée proposes to designate the microbic maladies of the endocardium under the name of "endocardies." It is clear that this affection has not for cause only one single microbe, but that every infectious malady may by its interior parasitic products become endocardiac. There is no exception to the rule that endocarditis in the neighborhood of the aortic valves depends on the propagation of the divers degenerations of the arterial system. Limited space will not allow me to enter more fully into the various types of the diseases of the heart as described by the author, but I must refer your readers to the work itself, which will amply repay perusal. I may, however, remark that one may observe that, throughout the work under notice, physiology contributes a good deal to the interpretation of the morbid phenomena and their connection one with another. There is no group of maladies where the advantages of this method are more evident than in the diseases of the heart. Moreover, a large part of the work is devoted to the etiology and to the pathogeny of the lesions of this organ.

To give your readers an idea of the eclectic spirit of Professor Sée, I shall lay before them the summary of a series of lectures which he delivered a short time ago at the Hôtel Dieu, on which occasion he treated of iron and the various forms of anæmia. He pointed out how the ques-

tion of the action of iron in the organism is still under controversy and this is why no pharmaceutical rule for the divers sorts of medical preparations can be scientifically formulated. There is no absolute rule except for the therapeutic indications, which formally exclude from ferruginous medication all the forms of pseudo-anæmia; namely, (1) alimentary and atmospheric inanitions; (2) all kinds of exhaustion (muscular, nervous, secretory); (3) all intoxications, and all virulent or specific anæmias, such as syphilitic, tuberculous, paludal, and rheumatic pseudo-anæmia. It is only in true anæmia that iron is justifiable. There are three types, he said, of true anæmia; namely, anæmia of the hæmorrhagic origin, chlorosis, and anæmia termed spontaneous. He then referred to the physiology of iron in the organism, and to the formation of hæmoglobin, the mysteries of which are still enshrouded in obscurity. He does not approve of injections of iron, or of those of manganese, as they are eminently toxic, and produce a diminution of the sanguineous pressure, intestinal troubles, paralytic disorders of the central nervous system, and alteration of the kidneys. Nothing of the kind occurs by the ingestion of iron in the stomach, which absorbs nothing directly. The gastric juice transforms the iron into the chlorides, which, on their arrival in the intestine (which is alkaline), become soluble oxide in the presence of organic substances, then soluble carbonates of iron in carbonic acid and in organic matters. Finally, the compounds of iron, submitted to the action of sulphurets and other reducing agents, form sulphurets of iron which are eliminated by the fecal matters. The combinations of the oxide of iron with the organic acids or with the albuminates behave in the same way. The albuminates of iron in the presence of the hydrochloric acid of the stomach, are immediately decomposed in forming the chlorides of iron. It may, therefore, be concluded that the salts of mineral iron, instead of being directly annexed to the organism, are intended to protect in the intestine the combinations of organic iron, of meat for instance, against all decomposition. That which is certain, is, that iron does not appear in the urine under the form of an organic salt, but as an organic compound, and particularly as coloring matter, as shown by Harley of London.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 20, 1889.

Cities.	Estimated Population for 1889.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,804; under five years of age 1447: principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 952, consumption 259, acute lung diseases 115, diarrhœal diseases 758, diphtheria and croup 59, typhoid fever 42, whooping-cough 36, measles 17, cerebro-spinal meningitis 14, scarlet fever 13, malarial fever 12, erysipelas 1. From whooping-cough: New York 15, Boston 6, Philadelphia 5, Washington, 3, Baltimore, Worcester and Cambridge 2 each, Cincinnati 1. From measles: Cincinnati 7, Philadelphia 5, New York 4, Baltimore 2. From cerebro-spinal meningitis: New York, Cincinnati, Washington, Charleston, Taunton, Gloucester and Quincy 1 each. From scarlet fever: New York 7, Philadelphia 4, Baltimore 2. From malarial fever: New Orleans 6, Charleston 3, Philadelphia 2.

In the 28 greater towns of England and Wales with an estimated population of 9,555,406, for the week ending July 13th, the death-rate was 21.5. Deaths reported 3,937: infants under one year 1477, diarrhœa 640, measles 104, whooping-cough 80, scarlet fever 43, fever 39, diphtheria 38.

The death-rates ranged from 12.9 in Huddersfield to 31.8 in Newcastle-on-Tyne; Birkenhead 22.4; Birmingham 22.6; Bradford 22.9; Bristol 16.4; Hull 22.3; Leeds 25.8; Leicester 28.1; Liverpool 24.6; London 19.3; Manchester 26.7; Nottingham 20.4; Sheffield 23.3; Sunderland 30.3.

In Edinburgh 16.6; Glasgow 22.4; Dublin 16.3.

The meteorological record for the week ending July 20, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 20, 1889, TO JULY 26, 1889.

GARDNER, WILLIAM H., major and surgeon. By direction of the Secretary of War, detailed to attend the encampment of the National Guard of the District of Columbia, at Fort Washington, Md., from July 22d to 29th, 1889, for the purpose of giving instructions to the medical officers and hospital corps in their respective duties. Par. 1, S. O. 164, A. G. O., July 18, 1889.

STEINMETZ, WM. R., captain and assistant surgeon, now at Baltimore, Md., on leave of absence on account of disability, by direction of the secretary of war, will report in person to the commanding officer of the Watertown Arsenal, Mass., for duty at that station, relieving Lieutenant Colonel James C. McKee, surgeon. Par. 3, S. O. 166, A. G. O., July 20, 1889.

MCKEE, lieutenant colonel. On being relieved at the Watertown Arsenal, will repair to Philadelphia, Penn., and assume the duties of attending surgeon and examiner of recruits in that city. Par. 3, S. O. 166, A. G. O., July 20, 1889.

ROBINSON, SAMUEL Q., captain and assistant surgeon, U. S. A., Fort Hamilton, New York Harbor, Leave of absence for two weeks is hereby granted. Par. 11, S. O. 165, Headquarters Division of the Atlantic, July 22, 1889.

BALL, R. R., lieutenant and assistant surgeon, U. S. A. Leave of absence granted in S. O., Headquarters Department of the Missouri, July 9, is extended five days. Par. 1, S. O. 167, A. G. O., July 22, 1889.

PROMOTION.

EWING, CHARLES B., assistant surgeon. To be assistant surgeon with the rank of captain, after five years service, in accordance with the act of June 23, 1874. July 5, 1889.

By directions of the President, the State of Arkansas, embracing Little Rock Barracks, is transferred to the Department of the Missouri. General Orders No. 66, Headquarters of the Army, A. G. O., July 19th, 1889.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE.

OMITTED FROM LAST ANNOUNCEMENT.

VANSANT, JOHN, surgeon. When relieved, to proceed to Mobile, Ala. July 11, 1889.

MEAD, F. W., passed assistant surgeon. Relieved from duty as acting chief clerk and attending surgeon; ordered to St. Louis, Mo. July 11, 1889.

WILLIAMS, L. L., passed assistant surgeon. Relieved from duty at Cape Charles Quarantine Station; ordered to Baltimore, Md. July 10, 1889.

WEEK ENDING JULY 20, 1889.

KALLACH, P. C., passed assistant surgeon. Granted leave of absence for thirty days. July 15, 1889.

PETTUS, W. J., assistant surgeon. When relieved, to proceed to Marine-Hospital, Boston, Mass., for duty. July 18, 1889.

WOODWARD, P. M., assistant surgeon. Granted leave of absence for thirty days, July 15, 1889.

VAUGHN, G. T., assistant surgeon. Relieved from duty at Boston, Mass.; ordered to Norfolk, Va. July 18, 1889.

STONER, J. B., assistant surgeon. Granted leave of absence for twenty-five days. July 15, 1889.

GEDDINGS, H. D., assistant surgeon. Relieved from duty at Baltimore, Md.; ordered to Key West Quarantine Station. July 18, 1889.

WERTENBAKER, C. P., assistant surgeon. Relieved from duty at Norfolk; ordered to Galveston, Texas. July 18, 1889.

GROENEVELT, J. T., Commissioned as assistant surgeon, July 11, 1889; ordered to Gulf Quarantine Station for temporary duty. July 20, 1889.

SOCIETY NOTICE.

THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS. — This Association will hold its next annual meeting at the Barnet House, Cincinnati, O., in the rooms lately occupied by the Military Order of the Loyal Legion, on Tuesday, Wednesday, and Thursday, September 17, 18, and 19, 1889. No formal invitations will be issued to non-members, but the Association hereby extends a cordial invitation, to such members of the profession wherever resident as may feel interested, to attend the meeting and participate in the proceedings. The papers and discussions will embrace subjects pertaining to obstetrics, gynecology, and abdominal surgery. By order of the President.

WILLIAM WARREN POTTER, *Secretary*.

BOOKS AND PAMPHLETS RECEIVED.

Book on the Physician Himself, and Things that Concern his Reputation and Success. By D. W. Cathell, M.D. Ninth Edition revised and enlarged. Philadelphia and London: F. A. Davis. 1889.

Bureau of Education. Contributions to American Educational History, Nos. 3, 4, 5, 6, 7. North Carolina, South Carolina, Georgia, Florida, Wisconsin. Washington: Government Printing-Office. 1888-89.

Lectures on Pathological Anatomy. By Samuel Wilks, M.D., F.R S., and the late Walter Moxon, M.D., etc. Third Edition, thoroughly revised. By Samuel Wilks, M.D., etc. London and New York: Longmans, Green & Co. 1889.

The Urine, the Common Poisons, and the Milk. Memoranda, Chemical and Microscopical, for Laboratory Use. By J. W. Holland, M.D. Illustrated. Third edition, revised and much enlarged. Philadelphia: P. Blakiston, Son & Co. 1889.

Munich a Healthy Town. Two Reports by Drs. M. von Pettenkofer and H. von Ziemssen, Munich, 1889. Reprint.

University Medical College of Kansas City (Formerly Medical Department of the University of Kansas City, Missouri). Ninth Annual Announcement and Catalogue of Sessions, 1888-89.

First Annual Report of the Methodist Episcopal Hospital, Brooklyn, N. Y. Covering a period of ten and one-half months, and ending October 31, 1888, with its History, Charter, etc.

Annual Announcement with List of Graduates from 1874 to 1889 inclusive, of the Hospital College of Medicine, Medical Department of Central University, Louisville, Ky. Session of 1890.

Cystoscopic Explorations by A. V. L. Brokaw, M.D., Demonstrator of Anatomy in Missouri Medical College, Assistant to the Chair of Surgery and Senior Assistant Surgeon St. John's Hospital, St. Louis, Mo.

THE ANATOMICAL APPEARANCES RESULTING FROM POISONING BY ARSENIC.[1]

BY F. W. DRAPER, M.D.,
Assistant Professor of Legal Medicine in Harvard Medical School.

THE notes presented in this brief paper relate solely to that class of cases of arsenical poisoning which may be properly designated as acute—cases, in other words, in which death follows a single toxic dose of arsenious acid after an interval of time not exceeding forty-eight hours. The anatomical appearances here described will be, in the main, such as the writer has himself observed in his inspection of the dead bodies of persons who have killed themselves with arsenic. In these observations, the toxic effects of this poison have seemed to take a wider range and a more comprehensive character than the standard text-books of toxicology would lead one to believe. The writers with whom students of forensic medicine are most familiar, such as Taylor, Guy, Casper and Reese, give the distinct impression that arsenical poisoning is essentially an affair of the stomach and intestines, and that other organs and regions have either no interest at all, or an interest so remote as to be hardly worth mentioning. The appearances which the gastric and intestinal mucous membrane presents are generally described with great particularity of detail; and the color-effects, the red evidence of "irritation," are especially elaborated to impress the memory; for to nearly all authors of toxicological works, arsenic is a typical "irritant" poison, and, being such, its characteristic effect should be inflammatory redness. Moreover, it is fair to state that toxicologists are usually distinguished as chemists, not so much specially interested in the anatomical appearances of organs as in the best methods of recovering the largest amount of poison from those organs; if they see anatomical specimens from the victims of arsenic, it is not usually at the autopsy-table, but after an interval of hours or days, when the organs are submitted to them in the chemical laboratory, and after exposure to air and the conditions favoring decomposition have materially modified the original appearances. It is for these reasons that the descriptions which are given in the standard text-books on poisons, so far as they relate to the post-mortem appearances left by arsenic, are incomplete and unsatisfactory. I shall be pardoned, therefore, if in addition to the mention of certain anatomical features of arsenical poisoning, well-known because oftenest found in the books, I include other features less familiar, but scarcely less interesting or important, which I have personally noted.

Let us suppose, now, that the dead body of a man is found. He has taken a quantity of arsenious acid in secret with suicidal purpose, and has carefully destroyed all the evidences of his act and intent. He has died without antidotal treatment, and his dead body affords the only present available proof of the cause and manner of the death. What are the indications which the medical examiner finds at the autopsy to suggest to him that arsenic was the lethal agent, and to guide him as to the propriety of chemical confirmation of his post-mortem diagnosis?

It is not to be understood that these data for diagnosis are uniform in kind or in degree in all cases; in this respect, arsenical poisoning is not different from most pathological processes. The changes which result from the ingestion of a fatal dose of arsenic are subject to manifold modifications. The state of the stomach in its relation to the last meal of food, the amount of its fluid contents, and other conditions interfering with the direct disposal of the poison, will at once occur to the mind as factors to control the post-mortem appearances. Time, too, is an important element in the matter; the interval between the ingestion of the poison and the death of the patient, and the interval between the death and the autopsy, ought to be considered in this connection. But perhaps the most striking modification, and one that is not sufficiently noted in descriptions of the stomach and intestines after arsenical poisoning, is that due to the treatment which the patient receives. Much of the so-called "inflammation" in these cases is caused, without doubt, by the arsenic; but not a little of the redness of the mucous membrane is more readily traceable to the mustard and other emetics, to the iron and other antidotes, to the irrigation and other measures designed and applied with proper vigor and assiduity for the relief of the patient. Of the arsenical stomachs which I have seen, that one best fulfilled the description of the text-books which had received during the life of its owner copious doses of hydrated sesquioxide of iron urged upon her as long as she could swallow during the nine hours which intervened between her poisoning and her death.

Avoiding in our review of the post-mortem appearances referable to arsenic this and other sources of error as far as we can, let us study the anatomical changes which an uncomplicated case of acute poisoning would probably present.

Externally, the body would present but few indications of the cause and manner of the death. The facial expression usually suggests suffering in the last moments of life, in harmony with the characteristic clinical course of events. The degree of post-mortem rigidity is marked. If the subject is plethoric, widely extended patches of livid discoloration occupy the dependent parts of the body; sometimes, the dull bluish color of these lividities is replaced, in part, by a rosy red, a change particularly noticeable if the autopsy is delayed. The skin frequently shows another change from its normal post-mortem color or pallor, and this consists in a sallow or yellowish hue, suggesting icterus. I have observed in some instances a narrow line of ecchymosis upon the prolabial mucous membrane, that of the lower lip especially, to be explained probably as an incident of the clinical history of the poisoning, as it was most marked in cases in which vomiting was a marked symptom. Exceptionally, the tongue is seen to be reddened, but otherwise the cavity of the mouth and pharynx presents nothing remarkable.

Turning now to the internal parts of the body, let our examination take the usual course, as if we had no clue to the cause of the death and our inquiry of the several organs was to determine that clue and establish the diagnosis. Orth says:[2] "In medico-legal cases, in which a well-founded suspicion may be formed as to the cause of death, the rule is to begin with that cavity in which the suspected changes are to be found." In our present study we assume that we are not in

[1] Read before the Massachusetts Medico-Legal Society, October 3, 1888.

[2] A Compound Diagnosis in Pathological Anatomy, p. 40.

possession of this "well-founded suspicion," but that we approach our inspection without any bias or preconceived theory.

The brain and its envelopes will give us negative information. Although the brain is said by some chemical authorities to have a special affinity for arsenic, and that hence it has very great value as material for chemical examination, the presence of the poison does not leave any characteristic objective impress upon the organ. Most of the authors on toxicology make no mention of this region in describing the anatomical appearences due to arsenic; if any note at all is made, it is to remark that "congestion" is sometimes observed. In my own cases, the injection of the cerebral and meningeal vessels has been remarked mainly in cases in which morphia was used to allay the toxic symptoms.

The organs of the thoracic cavity next demand our attention. In cases in which death has followed quickly after the ingestion of a fatal dose of arsenic, the heart escapes injury; the color and consistency of its muscular tissue remain normal. But if life be prolonged beyond eight or ten hours, parenchymatous changes are developed, and the normal red color of the ventricular walls becomes changed to pale or yellowish, while the consistency of the muscular tissue is diminished and is friable under pressure, a condition betokening fatty degeneration. Just when this change in the cardiac muscle begins, it is difficult to state with definiteness; it is an early effect of arsenical poisoning and coincides with the absorption of the poison into the blood. It is certainly a rapid change and must be one of the factors in the cause of death. I have seen it in a case in which death followed after an interval of six hours; and, on the other hand, it was not manifest in the heart of a young woman who survived ten hours.

Another appearance in the heart, and one that I have been disposed to consider as characteristic of arsenical poisoning, is the presence under the endocardium of the left ventricle of ecchymoses, not larger than a dime and usually limited to the posterior wall or the interventricular septum. These ecchymoses are generally single, and they rarely exceed two in number. In depth they are superficial, section displaying simply a thin layer of blood under the endocardium. In one instance I have seen ecchymoses on the external surface of the heart under the visceral pericardium; they were about the size of a split pea, and were found mostly on the upper part of the left auricle between the aorta and the appendix auriculæ.

The blood in most cases is dark in color and fluid in consistency, whether it be observed in the right ventricle or in the large arteries. It is described as "syrupy" by some writers, but my cases have not yielded a result that could be designated by that term, unless the syrup were understood to be very thin.

Writers on poisons have not found anything noteworthy to state concerning the lungs, with reference to their appearance after death by arsenic. Yet there are one or two features growing out of the condition of the blood that seem deserving of mention. The fluid state of the blood permits its ready gravitation to the dependent portions; hence we generally find an unusual degree of hypostatic blood-supply. In some cases, the blood takes on color-changes which show best in the lungs; the anterior and upper portions are of a florid, almost vermilion hue; while the posterior and inferior parts retain their dark purple. The appearance of the lungs in these instances is not unlike the effect produced by carbonic-oxide poisoning. Another phenomenon referable to the blood is the presence of capillary hæmorrhages under the visceral pleura; these are few in number, varying in size from that of a mere point to that of a grape-seed, and they are usually limited to the lower parts of the lung and to the fissures.

Turning now to the abdominal group of organs, and following in our description the usual order, we note, in the first place, that the vessels of the peritoneum, in our hypothetical case of arsenical poisoning, are almost invariably injected to a marked degree.

The spleen gives us nothing of value in our search for data; so far as our present inquiry is concerned, it is of no service to us.

The kidneys present an interesting degenerative alteration, which has received less attention than it has deserved. In proportion to the length of time which has elapsed between the ingestion of the arsenic and the fatal result, these organs will be found to display, in greater or less degree, the evidences of parenchymatous change, due probably to the irritant action of the poison circulating in the blood and seeking an avenue for elimination. At first this change manifests itself in the form of "cloudy swelling," so-called, in which the kidney loses its normal grayish-red color and its firmness, becoming pale and soft and increasing somewhat in size. These changes progress till true fatty degeneration takes the place of the granular degeneration of the earlier stages, and the organ is yellowish gray, flaccid and enlarged. Its section shows a somewhat thickened cortex, yellowish gray in color, with marked opacity, and presenting yellow streaks and spots indicating fatty degeneration of the tubules. The contrast between this portion of the organ and the appearance of the medullary pyramids is distinct because the vessels of the latter are relatively full. Upon microscopic examination, the granular epithelium of the tubules shows an increase in its granular elements, with indistinctness of their nuclei.

These changes begin and go forward with remarkable rapidity, coinciding in this respect with the analogous degeneration of the muscular tissue of the heart. All conditions which favor the ready absorption of the arsenic promote the parenchymatous changes which have been described. In the case of a girl of sixteen, who took a box-full of "Rough on Rats" in water on an empty stomach, and died eighteen hours later, I found the kidneys presenting the characteristic appearances of the earlier stage of fatty degeneration. On the other hand, these appearances were absent from the kidneys of a young woman who died nine hours after swallowing half a box-full of the same handy preparation of arsenious acid.

The pelvic viscera yield no data that are of service in the post-mortem diagnosis of arsenical poisoning. Sometimes the bladder displays in its lining membrane some dull red spots, but these are neither constant nor characteristic.

The appearances presented by the œsophagus are of interest because the mucous membrane of this tube comes into intimate contact with the poison on its way to the stomach, and might well be expected to give local evidence accordingly. As a matter of fact, however, this canal is generally of normal appearance.

Rarely, there are patches or long narrow streaks of dull redness. In one case, in which the body of a woman was exhumed for examination ten days after her death, I observed some bright yellow deposits on the mucous membrane of the gullet, the result of the action of the sulphuretted hydrogen of decomposition upon the arsenious acid.

The stomach is the one organ which before all others possesses in the eyes of most medico-legal observers a paramount importance. It receives the poison immediately upon its ingestion, offers its extensive expanse of mucous membrane to the local action of the irritant, engages actively both in assimilating and in rejecting the unwelcome guest and takes in, as well, a variety of agents designed to expel or neutralize the toxic material. It is not strange, therefore, that the post-mortem appearances presented by this organ after a fatal dose of arsenic should have challenged the close attention of medico-legal pathologists. These appearances take a wide range in kind and degree. On the one hand, it is not a very rare occurrence to find a stomach which has suffered no damage whatever by receiving a poisonous dose of arsenic; so far as its gross appearances are concerned, it shows a surprising immunity from the effects which are supposed to be typical; and, studied by itself, it would readily be pronounced normal. On the other hand, we find appearances indicating to the fullest degree the irritant action of the poison, general redness, either of a bright scarlet hue or more often of a dull brownish shade, diffused and confluent in extensive patches of submucous ecchymoses or arranged in parallel streaks which on closer examination are found to represent series of minute hemorrhagic dots. Between these two extremes, each of which has but relatively few examples to illustrate it, we find all degrees and varieties. A common observation is to find the mucosa thrown into long folds or rugæ by the contractions of the muscular coat of the stomach, and these rugæ are marked at their summits by dull, brownish-red discolorations, or present numerous transverse red lines arranged so closely together as to give the effect of a continuous longitudinal streak. The part of the stomach mostly involved in the change is the pyloric end, and here the redness indicating submucous extravasation is generally diffused, giving the surface something like the appearance of red velvet. Occasionally, one is fortunate in finding deposited on the mucous membrane unmistakable evidence of the cause of death, in the form of thick, pasty, whitish-gray patches which are firmly adherent; these are surrounded by a line of vivid crimson, and if the pultaceous mass is carefully scraped away, the underlying mucous coat will be found to display a similar intensity of inflammatory redness, but without the erosion characteristic of an ulceration. Examination of the pasty material with a good lens reveals the typical crystals of arsenious acid. Besides this adventitious lodgement of the poison upon the gastric mucosa, one sometimes finds large areas of the surface covered with a layer of thick tenacious mucus, giving a suggestion of diphtheric exudation. There is, moreover, a swelling of the mucous membrane, demonstrated by the obliteration of the normal line of demarkation between the œsophagal mucosa and that of the stomach. The microscope detects in the gastric glands changes which correspond with those already described in connection with the heart and kidneys; namely, cloudy swelling of the cells lining the glands, followed at a later stage by their fatty degeneration. It is, perhaps, needless to add that the changes in the stomach due to arsenic are confined to the mucous coat, the muscular and serous coats escaping injury.

The contents of the stomach in arsenical poisoning deserve a passing word. Notwithstanding the violent vomiting which forms such a predominant clinical feature in these cases, the stomach is never found empty, but the amount of matter which it retains is often sufficient to excite surprise. Generally the contained matter consists of a pint or more of thin grumous fluid, brownish-red in color and without odor. Sometimes this fluid has a distinctly reddish tinge from the blood which it contains; if it be placed in a glass jar and allowed to stand a few minutes, this blood-stained portion forms a layer at the bottom, and its hæmorrhagic character is more easily demonstrated. An occasional feature in the gastric contents is the presence of white, soft, flocculent masses floating in the fluid.

The intestines present appearances which are analogous to those just described in connection with the stomach, but in general they are less striking; moreover, lesions of the gastric mucosa and those of the intestinal tract do not correspond in degree in the same subject, for it is not unusual to find typical hæmorrhagic gastritis fully developed, with scarcely any alteration of the intestinal coats. Of all parts of the small intestines, the duodenum shows the effects of arsenic most frequently and most satisfactorily; we observe here the same redness of submucous ecchymosis which the lining of the stomach presents. The summits of the mucous folds are especially the seat of the change; and here, too, one sometimes sees small patches of vivid crimson overlaid with a white pasty deposit, marking the lodgement of the arsenic. Other parts of the intestinal mucosa offer no constant lesion; it is most often found reddened in larger or smaller areas somewhat widely distributed. It is an error to fancy that arsenic leaves its irritant traces uniformly, and that in fatal poisoning by that agent there is in the intestinal lining a general diffused inflammatory redness from the pylorus to the cæcum; such wide-spread effects are occasionally seen, but they are the rare exception.

The contents of the small intestines are fluid, and in general resemble thick rice-water, through which are distributed flocculent lumps of soft whitish matter, and sometimes masses of the poison itself in the form of white, pultaceous collections. If the hæmorrhagic lesion of the gastric and duodenal mucosa is very marked, the blood which has escaped in consequence will give a brownish-red hue to the contents of the intestines.

The colon and rectum are almost always found contracted and empty, with a soft, swollen, grayish lining membrane, covered with white stringy mucus. The redness which is observed in the small intestine and the stomach is not continued in the lower bowel except in protracted or chronic cases of poisoning. It has not been my fortune to observe it in any acute case.

Last and largest in the list of organs which we question for evidence of poisoning, is the liver, the special store-house of the lethal agent. The one characteristic change wrought by arsenic consists of fatty metamorphosis, a change analogous to that ob-

served in the heart and kidneys. In gross appearance, we find the liver slightly increased in size, if changed at all, rather firmer in consistency than in the normal state, and displaying externally and on section circumscribed yellow areas; or, if the change has gone forward to an extreme degree, the entire organ presents a uniform light-yellow color having wholly lost its normal reddish-brown. Here, again, as in the heart and kidneys, the change is a rapid one, a few hours sufficing to reduce the organ from its normal state to a condition in which fatty degeneration and fatty infiltration are associated, the former a late stage of parenchymatous (granular) inflammation, the latter an incident thereto.

This review of the anatomical appearances left by arsenic upon the human body leads directly to the question which is of paramount medico-legal importance; namely, Is post-mortem diagnosis of arsenical poisoning an easy matter? That is to say, assuming, as we assumed at the beginning of this paper, that we are in the presence of a dead body of whose clinical history we know nothing, are the revelations of the autopsy sufficiently characteristic and unequivocal to warrant one in concluding readily that the death was by arsenic? The answer is in the affirmative, upon the single condition that the data are studied in their associated relation, and that their collective significance is the evidence which guides the examiner. There is no single organ whose testimony is sufficiently conclusive to control the diagnosis, with the possible exception of the finding of deposits of the poison upon the gastric mucosa, with a marked degree of inflammatory redness beneath and around them; but short of this, the condition of the stomach, however striking its inflammatory character may be, is suggestive only, the various degrees of irritant effects being explainable by numerous causes other than arsenic. But when, in addition to the presence of gastritis, one finds fatty degeneration of the heart, kidneys and liver, a fluid and dark condition of the blood, and sub-endocardial ecchymoses, he may with clear conscience testify in court that he is of the opinion that the death was by arsenic. In this conclusion, he would probably be confirmed by the results of a properly conducted chemical examination of the viscera. Indeed, without the gastric and enteric data, or with only an insignificant and equivocal degree of inflammatory reddening of the mucous membrane of the digestive tract, the concurrence of fatty changes in the heart, kidneys and liver should arouse the examiner's suspicions, and suggest to him the propriety of seeking the chemist's aid to verify his surmises.

In this paper, I have purposely refrained from discussing controverted questions relating to arsenic and its effects on the system, preferring to set forth in as clear and intelligible a manner as possible the anatomical data of acute arsenical poisoning as I have observed them or as they are agreed upon by standard authors, rather than to indulge in the examination of speculative points or to quote the diverse opinions of various writers upon unsettled problems pertaining to the main theme. Certain incidental topics, too, like the influence of arsenic on putrefaction, the technical methods of conducting a medico-legal examination in a case of arsenical poisoning, and the proper way of preserving and transmitting material for chemical examination, have been purposely omitted. If the simple and uncomplicated sketch here offered shall serve to promote the practical aims of legal medicine as represented in this Society, its design will have been fulfilled.

CEREBRAL SYMPTOMS CONNECTED WITH PHTHISIS.[1]

STATISTICAL PART OF THE PAPER.

BY J. B. AYER, M.D.

IN 1863, Dr. Clouston described a form of mental disease characterized by special symptoms, to which he gave the name of "Phthisical insanity." He stated that two to three per cent. of phthisical cases were followed by this form of insanity; but in looking over the McLean Asylum Reports eleven years ago, I found only five cases out of 5,116 attributed to phthisis, and in asylum reports generally, I find very few cases tabulated as of phthisical origin.

To aid in determining to what extent the adult brain is affected in phthisis, I have inquired into the history of one hundred and fifty-four cases of pulmonary consumption at the Channing Home, which have came under the care of Drs. Mason, Rotch, V. Y. Bowditch, Lovett and myself with the following results: twenty-five had mental disturbance; three others had convulsions; six others had the unreasonable assurance of improvement characteristic of spes phthisica, — the delirium of hope.

MENTAL DISTURBANCE.

CASE I. Miss M., twenty-three years of age, had been a patient at Danvers Asylum, making a good recovery. After her discharge she worked several months in a family, and then (March, 1886) began to cough. She entered the Home, September, 1886, and remained till April, 1887. She was reasonable when she entered, but toward the end of her stay had an attack of melancholia, and would speak to no one. She could not be cared for at the hospital, but was taken to her home, where she recovered from the mental symptoms in the course of nine months. Phthisical disease is steadily progressing, and she is emaciated and much troubled with coughing.

CASE II. Mrs. E., thirty-one years, Swede. Phthisis of one year's standing. On account of delusions left the Home abruptly at the end of nine days. Dr. A. L. Mason saw her afterward, and found it was necessary for protection to remove the children from the mother. Subsequent history unknown.

CASE III. Mrs. L., twenty-eight years, Swede. Advanced phthisis. She has had delusions due to that disease. She turned against her husband and against the Home, and was discharged at her own request at the end of ten weeks. She applied for re-admission but was declined on the ground of insanity.

CASE IV. Miss M., thirty-seven years at time of death. Phthisis of eleven years' standing. She never had a sound mind, and was partly demented during her stay of many years at the Home. The dementia was aggravated by pulmonary disease.

CASE V. Mrs. B., twenty-eight years, entered Home, July 3, 1880, with advanced phthisis of eighteen months' standing. No important change followed admission except that hallucinations of hearing de-

[1] Read before the Boston Medico-Psychological Society, January 17, 1889.

veloped. She imagined that patients in the lower ward were conspiring against her. On this account she desired to leave the Home, and was discharged.

Case VI. Mrs. C., twenty years. Phthisis dated from May, 1881. She left the Home, April 6, 1882, on account of hallucinations of hearing. She felt that we were going to kill her. She was admitted to the City Hospital, and again taken back to the Home. She became quite clear, and disturbed no one during the last four weeks of her life. She died in June, 1882.

Case VII. Mrs. Mary S., thirty-eight years. The wife of a physician who had been Mary's employer, writes: "Mary had been most respectful and amiable; but three years before her death she changed her manner, would speak abruptly and at times was abusive. During several months these were the only symptoms noticed, and only at a later date was lung trouble discovered." In the Home she was querulous, suspicious of patients, and said that her brothers were persecuting her. She felt that people were coming into the kitchen and talking about her in an unfriendly way. She died at the Home in May, 1888, (after seven months' residence there). During the last month of life she was quite clear in mind, and seemed anxious to make amends for all the trouble she had caused.

Case VIII. Mrs. D., forty-two years old when she entered in December, 1883. She found fault with the patients, and would, without provocation, suddenly throw her food across the table. She complained that her mug of milk was not of as good quality as that of the other patients. She thought her food was poisoned. She would astonish visitors by "putting on airs." Nevertheless, she was able to remain in the Home two years and nine months, at last developing tubercular peritonitis. During the last six weeks of life her delusions had for the most part disappeared, and she became tractable again.

Case IX. Miss P., twenty-five years of age, left the Home January 21, 1881, on a bitter cold morning, saying that she was in great trouble. She also took sudden leave of other homes and hospitals. Hallucinations of hearing.

Cases X. XI, XII. In these three patients the mental symptoms were those of extreme uneasiness with a desire to abruptly change their residence.

Case XIII. Mrs. M., fifty-six years. Phthisis began in 1880. She was admitted in August, 1884, and died November, 1884. During the last few weeks of life she became noisy, and disturbed other patients by praying in a loud voice and on all occasions.

Cases XIV, XV, XVI, XVII. These four patients had delusions about food, etc. Occasionally abusive.

Case XVIII. Miss F., thirty years. Phthisis of eight months' duration on entrance. She lived three months in the Home and greatly annoyed the other patients by scolding her cough in a loud voice. "Bad manners to you," she would exclaim in addressing her cough. Toward the end of life she became deaf, and was more quiet, but did not become clearer in mind.

Case XIX. Miss B., thirty-three years, would not permit her family to know her whereabouts. She left the Home ten days before her death, giving this reason, "I do not wish Mary (one of the patients) to have the opportunity of saying that I am laid out in a coffin down stairs."

Cases XX, XXI, XXII. All three patients began to wander in mind during the last four weeks of life.

Case XXIII. Mrs. G., forty-two years, died at the Home three months after admission, and twenty-one months after the disease began. Three years before death she began to scold, which was the first symptom. It was not an annoying form of insanity. She talked about ghosts and imaginary people visiting her. At table she would forget that she had been served and would say in the mildest possible way, "nobody has waited upon me." Hallucinations and delusions continued to the end of life.

Case XXIV. Mrs. C., twenty-five years. Phthisis lasted twenty months. She interested patients with wild romances about herself. At times she regarded herself as an exalted personage.

Case XXV. Mrs. M., twenty-seven years. Came from Lying-in Hospital five weeks after confinement, and died two weeks after admission. Mild delirium, constantly trying to get out of bed.

CONVULSIONS.

Case I. Miss O'B., had epileptic attacks at the age of five, and when she entered the Home, September, 1879, one year after the appearance of phthisical disease the epileptic attacks occurred once in two weeks. She died in October, 1885. Her mind was always clear except during the attacks which occurred at rarer intervals as the pulmonary disease progressed.

Case II. Mrs. B., twenty-five years, entered April 8, 1884, with extensive disease of both lungs dating from July, 1883. Convulsions began April 28, 1884. She died June 6, 1884. Four convulsions in all.

Case III. Miss C., now forty-eight years, coughed since 1871. Spinal deformity and active lung disease when admitted to the Home in 1881. Pulmonary disease has progressed very slowly since admission. In September, 1886, she began to be forgetful and to have epileptic convulsions which now occur once in two or three weeks. She is at times greatly confused and does not recognize her physicians. Approaching dementia.

SPES PHTHISICA.

At least six of the one hundred and fifty-four patients clung to a hope which under the circumstances was most unreasonable.

One patient upon the day of her death insisted upon being dressed and upon walking across the room without help. She could not realize how weak she was and kept asserting that she was going to get well, and would burst into tears if any patient hinted that she might not recover.

Another patient, forty-nine years of age, was in the habit of visiting a mind-cure physician and always returned in a happy state. Although hardly able to stand she would report "They tell me there is nothing the matter with me, so I know I am going to get well." Three days before her death she left the Home for fear of "taking consumption."

This proportion of cases of marked Spes Phthisica is undoubtedly small when compared with the experience of private practice.

Dr. Mason explains this circumstance by the fact that most of the patients had been informed previous to their admission that their condition was either serious or incurable.

In many of the cases a strange indifference regard-

ing the state of their health was noticed, and, as a rule, there was less anxiety shown regarding their condition than one would expect.

In explanation of most of these cases of mental disturbance it is not necessary to assume a tubercular deposit in the brain for tubercular meningitis in the adult is not of frequent occurrence.

Probably anæmia, œdema of the brain and the hectic condition will account for most of the cerebral symptoms described.

No *special form* of brain disorder existed in these cases; on the contrary there was the greatest variety of mental disturbances ranging all the way from insanity adapted to asylum treatment down to the mildest form of delirium and the enviable "delirium of hope."

There were no *constant* delusions nor hallucinations. Suspicion, uneasiness, and desire for change were most frequently noticed.

In two of the cases the mental symptoms preceded by several months the discovery of pulmonary disease.

In four cases the mental disturbance *commenced* during the last month, while in three cases the mind grew clearer during the last four weeks of life.

As we ordinarily see consumptive patients in private practice, the proportion of these cases showing mental disturbance may seem a large one, but it must be remembered that a Consumptive's Home affords an excellent opportunity to study cases allowing a continuous oversight of the patients, and generally for a long period.

COPAIBA IN SURGERY.

BY H. H. A. BEACH, M.D.,
Visiting Surgeon to the Massachusetts General Hospital.

IN the long-continued use of copaiba as an internal remedy, its value in surgical dressings may have been gradually lost sight of, until now it lies among the rubbish of forgotten things that excite only the interest of the antiquarian, its connection with a living and progressive art having in some unaccountable way become severed.

Some years ago, while reading the interesting description of "Medical, Surgical and Anatomical Cases," published by Lawrence Heister, in London, 1755, I was much impressed with the importance he attached to the balsam of copaiba in his dressings, and determined to test the drug in that capacity. It was accordingly applied to an indolent granulating surface, by first saturating charpie with the balsam, and after squeezing out the superfluous balsam, bandaging the charpie upon the ulcer. The unusually rapid growth of a handsome bed of rosy granulations, ready for the grafting process, was so clearly attributable to its use, that I continued to employ it, and finally adopted it as regular dressing to granulating surfaces in my hospital wards. It is simple, cheap, quickly prepared, and most satisfactory in its results. Its use has gradually spread to the wards of my colleagues at the hospital, and it is now an accepted dressing; being especially adapted to the flat, pale, granulating surfaces that commonly result from avulsions of the scalp, extensive burns and scalds, also for the cavities after operation for removal of necrosed and carious bone. It has succeeded in raising healthy granulating surfaces for grafting after other stimulating applications had failed. At the hospital it is applied with cotton-waste instead of charpie. The waste can be easily picked apart and cut into short bits by convalescents. The porous nature of the dressing permits a ready absorption of pus and of its partial disinfection by the copaiba, which imparts a fragrant balsamic substitute for the sourish odor of pus partly decomposed. On the chances that its activity as a dressing depended upon the copaivic acid which it contains, I have also applied that substance with a negative result.

PROGRESS IN DENTISTRY.

BY W. H. ROLLINS.

OBLIQUE-ROOTED TEETH.[1]

THIS abnormality, which is rare, has been observed exclusively in the upper first molars. The normal position of the roots of these teeth may be represented by three dots arranged in this way, ⁘ In oblique-rooted teeth the roots are arranged as follows, ⁛ The history of the extraction of these teeth is given, and the important point to remember is that in all attempts to extract, the forceps rotated. Whenever this rotation is met with in attempting to extract an upper molar, the operation should be postponed till a suitable instrument is ready, otherwise damage will be done to the other teeth or to the jaw.

PALATAL RUGÆ IN MAN.[2]

The conclusions of this writer are: The range of variation in the roof of the mouth and its folds is greater in persons affected with nasal catarrh than in those who are free from the disease. The variations in the rugæ are different on the two sides of the mouth. The excess of development of the premaxilla, and of the horizontal plate, especially the anterior portion, constitutes a condition which is found in about fifty per cent. of cases of nasal catarrh.

Nasal catarrh is found associated with so many phases of asymmetry of the rugæ of the hard palate and of the dental arches, that the disease should be studied as a morbid action which is based upon morphological elements, and not alone on climatic conditions.

STRUCTURE OF DENTINE.[3]

These experiments were suggested by those of Dr. Ord in etching the surfaces of mother-of-pearl and ivory by placing them in glycerine containing subcarbonate of potash. In order to apply this method to the dental tissues, a few experiments were tried, and as a result, it was found that not only other alkalies but also pure glycerine would produce the appearances, showing that the glycerine was the real active agent. To prepare for the experiments, freshly extracted teeth were ground and formed into thin sections, which were allowed to remain in glycerine for periods varying from one to six months. Examined with the eye, the teeth were found to be more transparent than usual. Under the microscope, the dentine bordering the pulp cavity was seen to present a fringed appearance, and was slightly laminated. Under a higher power, this was shown to be due to the dentinal tubes having lost the intertubular substance, the removal of this matrix leaving the tubes free; their course appeared interrupted at intervals

[1] Pearsall, in Journal British Dental Association, p. 38, 1889.
[2] Allen, in Dental Cosmos, p. 66, 1889.
[3] Bennett, in British Journal Dental Science, p. 1121, 1888.

by layers of membrane having a general direction parallel to the pulp. These layers looked like globular dentine. In this case, however, the globules were not solid, and the dental tubes could be seen crossing from one space to another. It is as yet too early to decide upon the significance of these appearances, but enough has been said to show the value of this new method of studying the hard tissues of the teeth.

TREATMENT OF POST-NASAL CATARRH.[4]

Seventy-five cases are reported, of which sixteen were cured by removing nasal obstructions. The importance of this treatment from a dental point of view, lies in the fact that the patients can use their noses to breath through. Where persons breathe through the mouth, the gums invariable become congested, recede, and the teeth become loose.

ANOMALOUS PAROTID DUCTS.[5]

There were six children in the family, three of whom had small openings just in front of the ear, from which there was a continuous discharge of saliva. On examination it was found that these openings were the outlets of the parotid glands. The other children had the openings of the glands in the normal positions. Inquiry showed that the abnormal openings were present in the cases of two cousins. All the other relations examined had normal ducts.

FUNCTIONS OF THE TONSILS.[6]

The significance of the various tonsils is in their relation to the blood-manufacturing system and to the outpour of copious secretions. The relations of the tonsils to the rest of the system can be well appreciated by comparing them with the relations of the sewage farm to the town whose refuse it makes use of, and to which it returns its elaborated products. If any of the secretions delivered to the tonsils become contaminated with irritating matters, whether generated in the system, or introduced from without, the tonsils in physiological correlation with the affected secretion show irritative changes.

STAPHYLORRAPHY.[7]

A return to this operation is recommended, instead of trusting to obturators as is usually done in this vicinity. His objections to obturators are that they require frequent removal to keep them clean, and that among the poor the expense of the apparatus prevents its use. In the same journal, Grant favors obturators, unless the operation for closing up the palate includes the introduction of new tissue by grafting between the edges of the cleft. He suggests that, if such grafting is resorted to, protection should be temporarily given to the lower surface by a plate of rubber or some other hard material.

EXCESSIVE ABSORPTION OF THE ALVEOLI A CAUSE OF NEURALGIA.[8]

The patient tried in vain to wear an artificial plate, but was unable to do so on account of the severe pain which it caused. An examination of the alveolar border of the lower jaw showed marked absorption, the inferior dental nerve coming so near the surface that the plate pressed upon it.

IMPLANTED TEETH.[9]

The results of implantation obtained by those operators who have given most attention to this new operation, are tabulated, and eighty-four per cent. reported as successful. The authorities differ as to whether the teeth become of the same color as the other teeth, and also as to the means by which the teeth become attached. On this latter point they are about equally divided between simple mechanical means, membranous attachments, and anchylosis.

DENTAL REFLEXES.[10]

Several interesting cases are reported of apparent diseases of the eyes caused by the teeth; namely, spontaneous dilation of the pupil, diagnosed as the beginning of locomotor ataxia, but which he cured by extracting a carious molar; a case of blindness, cured by extracting a tooth; asthenopia of the accommodation, cured by the extraction of two upper molars, which had been filled with gold; several cases of spontaneous movements of the eyelids in children, cured by lancing the gums or by the extraction of decayed teeth; ulcerations of the cornea, cured by lancing the gums during teething.

CARIES OF THE TEETH.[11]

The number of children reported as having been examined was 623, about equally divided as to sex. Of this number forty-eight had sound teeth. None of the children were over fifteen. The teeth examined were classified as follows:

SOUND TEETH	Temporary		3225
	Permanent		7600
			10825
CARIOUS TEETH	Temporary		1875
	Permanent		1944
		Total,	3819

This table shows that over thirty-four per cent. of the individual teeth were decayed.

The mixed saliva was also tested in each case, but no attempt was made to separately examine the saliva of the individual glands. The average of the chemical reaction between the ages of five and fifteen was 72.36% neutral, 25.64% acid, and 2% alkaline. Ottofy claims that decay is less frequent in cases of neutral than it is in cases of alkaline or acid saliva. I doubt this in cases of alkaline saliva.

I give in detail his results of examination of the saliva, as I know of no similar and extended examination.

TABLE SHOWING THE REACTION OF THE MIXED SALIVA AT VARIOUS AGES.

5 years.	75	% neutral.	25	% acid.	0	% alkaline.
6 "	61	"	39	"	0	"
7 "	61	"	39	"	0	"
8 "	84	"	14	"	2	"

[10] Galezowski, in British Journal Dental Science, p. 795, 1888.
[11] Ottofy, Cosmos, p. 15, 1889.

maximum at any age was thirty-four per cent., and the minimum sixteen per cent. At all ages, during the eruptive stages, caries was more prevalent on an average among the girls, by five per cent., than among boys. The total average at all ages among these children was twenty-seven and a third per cent. in males, thirty-two and two-fifths per cent. among girls, and thirty per cent. in both. This indicates that among the school children of this country thirty per cent. of the teeth are decayed before the age of fifteen, and shows how widespread a disease caries has become.

FILLING MATERIALS AS CONDUCTORS OF HEAT.

In cases of near approach to the pulp, the conductibility of the filling to be used should be carefully considered. Kells[12] has made a most important addition to our knowledge in this matter, through the introduction of his thermostat. This consists of a disk of zinc slightly concave and held rigidly at its edges by a hard rubber base. Through the back of the base is introduced a finely threaded screw, which almost impinges on the centre of the disk. The thermostat is placed in an electric circuit, which is broken by the want of contact between the zinc disk and the screw. To test the conductibility of the filling material, little cups are made of the different kinds to be tested, and water warmed to 140° F., is placed in them. One at a time they are placed on the zinc disk, and the time noted till the heat has expanded the zinc disk and closed the circuit, which is announced by a bell. By means of this machine he finds that gutta-percha is the only filling material which we have, that has a low power of conducting heat, and therefore that this is the only safe material to place near an almost exposed pulp. The oxyphosphates and oxychlorides are good conductors, and should never be placed near a pulp unless it is protected by a layer of gutta-percha one-sixteenth of an inch thick. No filling material at present known is so poor a conductor of heat as the natural covering of dentine and enamel.

OBTUNDING SENSITIVE DENTINE BY ELECTROLYSIS.[13]

Apply the rubber dam to the tooth, dry the cavity, soak in a six per cent. solution of cocaine in alcohol. Place the positive pole of a four-cell battery in the wet cavity, and apply the other pole to the cheek for three minutes. The writer claims that this completely destroys the sensibility of the tooth.

ELECTRICITY IN THE OPERATING-ROOM.

A writer in the *Dental Cosmos* makes the following suggestions as to the introduction of the electric current into the operating-room from the streets: The possibility of accidents demand the most careful construction of the apparatus, and the most thorough insulation of the motor for the engine and the mallet. There should be safety appliances to cut off any accidental augumentation of the current. Finally, as the current for the arc lights is more destructive than that from the Edison and similar dynamos, the current from the latter should always be taken when it is possible to obtain it.

COMBINATION FILLING.[14]

A matrix of thin German silver is to be applied to the tooth, and held firmly by suitable ligatures. Into the cavity thus made, amalgam is to be packed till the cavity is two-thirds full; then Steurers gold is packed against the amalgam till the gold ceases to lose its color, when the filling may be completed with gold foil. Dr. Clapp states that by means of this new crystal gold of Steurers, a filling can be built up out of gold and amalgam at one sitting that is better for cavities that extend under the gum than an all-gold filling. The time to make the filling is greatly reduced, and this is an important point, the filling is thought to be better than one entirely of amalgam, as this is apt to crack at the edges from mastication.

EFFECT OF NITROUS OXIDE.[15]

There is a progressive loss of carbonic acid in the gasses expired from the lungs under the inhalation of nitrous oxide. This is not associated with the accumulation of carbonic acid in the blood, and must therefore be due to diminished production in the tissues, or to defective absorption by the blood. In order that carbonic acid may be produced, free oxygen, or some substance capable of yielding it, must be present; but under nitrous oxide the free oxygen is displaced by nitrous oxide, which is not decomposed in the system; hence during the inhalation of nitrous oxide, the process of tissue metabolism and the production of free carbonic acid is in abeyance. What effect has nitrous oxide on the heart? Comparison of the pulse-trace taken from the same individual before and during the inhalation shows that during the height of anæsthesia, the number of strokes is increased; they have a greater height and greater sharpness of the initial curves and apices. Tidal wave is almost absent, while the dicrotic wave is accentuated, and farther from the apex of the trace.

NITROUS OXIDE AS AN ANÆSTHETIC.[16]

Nitrous acid has been said to produce anæsthesia in several ways. By entering the lungs and being split up into oxygen and nitrogen either in its passage through the pulmonary epithelium or in the blood or tissues through which the blood passes. In disproof of this splitting up, we have Frankland's experiments, which show that practically all the nitrous oxide can be recovered from the lungs, and also the experiments of Bert, which show that oxygen cannot produce anæsthesia; while Sanderson, Turner and others have proved that nitrogen cannot produce anæsthesia, if, therefore, nitrous oxide can produce this effect, which its constituents are incapable of producing, we may suppose it does not undergo decomposition.

Anæsthesia from nitrous oxide cannot be due to a deoxydation of the blood; for when you asphyxiate an animal by allowing him to breath into a long tube, no anæsthesia is produced, the animal remaining sensitive as long as alive. Buxton holds the view that nitrous oxide produces a specific effect due to its composition. The experiments of Bert, which have been mentioned in a former report on dentistry, seem to prove his view. Bert mixed oxygen with nitrous oxide, and thus was enabled to maintain complete anæsthesia for any length of time, a whole day, in some of his experiments.

Beside the effects I have already mentioned, there are others which may be mentioned in connection with the blood and circulation. Nitrous oxyde when

[12] Southern Dental Journal, p. 414, 1888.
[13] McGraw, in Dental Review, p. 169, 1889.
[14] Clapp, in Dental Cosmos, p. 870, 1888.
[15] Silk, in Dental Record, p. 466, 1889.
[16] Buxton, in British Journal Dental Science, p. 228, 1888.

it enters the blood becomes loosely associated with the hæmoglobin and myoglobin. The blood of animals under it show less oxyhæmoglobin, but as the blood exposed to the air readily gives up the nitrous oxide, the connection must be a slight one. The watery portion of the blood also absorbs the gas, but as yet there are no data which show that any changes are produced. The most important effect upon the circulation is due to its effect on the nerve centres that govern the heart. In the early stages the heart appears little affected, but later it is slowed to a slight extent. The force of each beat is increased, as before mentioned, and its regularity maintained. If the anæsthesia is pushed until respiration ceases, the heart still beats, the pulsation becoming gradually slower and at last ceasing. If artificial respiration is begun, the heart recovers its regular beating. The blood pressure in deep anæsthesia is lowered, but this is not progressive.

With regard to the injurious effect upon the kidneys, a point which has been raised against the gas, Buxton claims that, as the blood pressure is lowered and the bulk of the kidneys reduced, it is difficult to believe there can be any congestion in these organs.

So far as these elaborate experiments go, nitrous oxide is the safest anæsthetic known, and when given by Bert's method, the most perfect and lasting.

TEST FOR SULPHOCYANIC ACID IN THE SALIVA.[17]

Precipitate the mucus with alcohol, reduce the volume of the saliva by heat, dilute it with water, and add a few drops of an aqueous solution of cupric sulphate. This will immediately produce a fine emerald green color.

CHEEK PLUMPER.[18]

In certain cases of excessive absorption of the alveoli it is necessary to attach to the artificial teeth bunches to distend the cheeks, to restore the original contour of the face. These cheek distenders were the invention of Dr. Allen, but as they were hard and not movable, they interfered with the expression when the face was not in repose. Wall proposes to make them movable, so that they will follow all the motions of the muscles of the cheeks. He does this by making them of light and thin material, and attaching them to the plate by means of springs.

IMPRESSIONS FOR OBTURATORS.[19]

The ordinary or Suersen method is an attachment to the plate, and extends backward into the cleft. When the impression is to be taken, this projection is covered with soft gutta-percha, and placed in the mouth, the patient being directed to swallow and talk, so that the soft gum may be molded into proper form by the muscles of the soft palate and pharynx. The difficulty met with is in adjusting the backward extension of the plate, so that it shall not be distorted by the contraction of the muscles. The invention of Shenker consists in providing a round rod with a metal shield at the end, movable so that it can be adjusted to suit the muscles before the impression is taken. The contraction of the muscles of the pharynx pushes the shield forward, and when it is in the proper position it is fixed, and the impression can be taken with certainty.

CONCLUDING NOTES.

Dr. Andrews has accomplished a great feat in photographing the germs which produce decay. He has made sections of decayed teeth, and has been able to show by photography all the appearances described by Miller in his investigation of caries.

Black has published an extremely complete monograph on the periosteum and peridental membrane which should have been mentioned in my previous report, but could not be properly noticed at that time.

The friction between those dentists who believe patents unprofessional, and those who patent all their ideas and charge the profession for them, is greater this year than ever before; and it is difficult to see where the matter will end. Great efforts have been made by the Massachusetts Dental Society under the lead of Dr. Merriam, to introduce non-patented devices to the members of the profession, and to induce the dentists to purchase their materials of houses who are not in the Dental Trust.

The year is marked by the formation of a Dental Protective Association, the object of which is to raise a fund out of which to pay the legal expenses of the members who may be sued by the great companies which are gradually patenting about all the operations performed by dentists. This matter of patent rights is becoming more serious every year. There is no remedy for the present state of things. We must wait till the professional spirit prevents dentists from taking out patents and selling them. At present the majority of dentists believe in patents, and only object to them when they are not their own, and when they feel the effects in the shape of royalties and suits at law for infringments.

Clinical Department.

ULCER OF THE STOMACH, AND ITS COMPLICATIONS.[1]

BY I. J. CLARKE, M.D., HAVERHILL, MASS.

PATIENT, N. J. F., aged forty-two, office clerk. Came under my care October 20, 1883. Family history was good, and there was nothing in the patient's history to account for his disease unless it be the fact that he had formerly been intemperate. His health till within a short period prior to above date had been excellent.

Symptoms: There were the ordinary symptoms of a mild attack of indigestion. Patient complained of a pain just below sternum. The pain was believed to be gastric (gastralgia). There was distress after eating. An anti-dyspeptic mixture of pepsin, bismuth and nux vomica was prescribed. The uncomfortable symptoms increased in severity. Patient had a profuse hæmatemesis the evening after his first visit to my office; the loss of blood caused him to faint. This was followed by another hæmorrhage the next day, which much prostrated him. Five days afterwards there was a return of the hæmatemesis, which was followed by five more similar attacks; the loss of blood in all was estimated at more than four quarts. Great prostration, with loss of consciousness and general convulsions ensued. All food was witheld; hypodermic injections

[1] Read before the Essex, North District Medical Society, January 9, 1889.

of ergot and stimulants were administered; cold was applied externally; Monsell's solution was given by mouth, and nourishing enemata were resorted to. Opium was also given per rectum, and the patient was kept thoroughly under its influence. Under this treatment he recovered sufficiently to be removed to the City Hospital, Boston, where he made a fair convalescence.

I next saw the patient June 7, 1884; and from that time occasionally until the middle of December, 1885. During this time he complained more or less of his old trouble, but there was no return of hæmorrhage, and he was able to attend to his business.

In September, 1885, a consultation was held with Dr. F. Minot, of Boston, who confirmed the diagnosis of ulcer of the stomach. Dr. Minot did not see any reason to regard the patient's condition as complicated with malignant disease. Peptonized milk was suggested and pretty large doses of bicarbonate of soda. Patient was still able for several months to attend to his business, when one day he lost consciousness and was sent to the Massachusetts General Hospital. There was no hæmatemesis, although hæmorrhage was suspected. He remained in the Massachusetts General Hospital nearly five weeks.

I saw him again June 20, 1886; he was then suffering from indigestion, pain and flatulence, also vomiting and inability to assimilate but small quantities of food, which was given often, a spoonful at a time. There was marked emaciation and loss of strength. There was considerable dysphagia, the cause of which was obscure.

Dr. Minot again saw the patient July 15th. He did not see reason to change his diagnosis, no tumor was perceptible to palpation. Dr. Minot thought the prognosis very unfavorable. Peptonized foods were continued although nothing seemed to nourish. Food was generally vomited as soon as introduced into the stomach. Nutritious enemata were resorted to for four weeks prior to death. The pain became very severe, assuming the character of the pain of peritonitis, and death occurred August 30th.

The autopsy revealed a mild general peritonitis, more particularly in the region of the stomach and pancreas. The peritoneum was adherent to the stomach and pancreas. The coats of the stomach showed acute and chronic interstitial gastritis, and five ulcers, averaging about the size of a ten cent piece, also a scirrhous cancer involving the whole stomach and head of pancreas. Two of the ulcers were situated upon the anterior and three upon the posterior wall. Two were exactly opposite each other, about one inch from the pyloric orifice, these surfaces coming closely in contact. One may possibly have been caused by the irritating pus of the other. Both seemed to be in the same stage of cicatrization. Of the five ulcers present, three were healed, and presented a peculiar pale rugous appearance; they projected above the level of the surrounding tissues. The two that were in process of repair, showed a healthy granular condition, discharging a creamy pus, and were about half cicatrized. The walls of the stomach were about half an inch in thickness, and were transformed into a scirrhous tissue which projected here and there in the form of hard nodules which so obliterated the cavity of the stomach that it would not contain more than four ounces. The character of the disease invading the head of the pancreas was the same. Large accumulations of fæcal matter were found in the transverse colon, which accumulated in great measure from the persistent flatulence.

The above can hardly be looked upon as a typical case of ulcer of the stomach. Some may see reason to think that the cancerous disease was primary, and the ulcerous secondary. Leube says that the combination of carcinoma with round ulcers of the stomach is particularly interesting, not only from a pathologico-anatomical, but also from a etiological point of view. In 160 cases Dietrich found this combination eight times; in some of the cases, cicatrices of the healed ulcers existed unconnected with the cancer; in others the carcinoma appeared to be implanted upon an old ulcer. Waldeyer speaks of quite superficial nodules with an indurated, slightly granular, ulcerated base, which were with difficulty to be distinguished from simple round ulcers, even with the aid of the microscope; and he comes to the conclusion, "that there is no pathologico-anatomical reason why a process which at first is simply ulcerative may not in time be converted into a cancerous one, if the epithelial elements of the wall of the stomach instead of passively disintegrating, take part in the proliferation of the border of the ulcer." [2]

Reports of Societies.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

TWENTY-FIFTH Annual Meeting, held at the Pequot House, New London, Conn., July 17 and 18, 1889.

WEDNESDAY MORNING SESSION.

The Society was called to order by the President, DR. WILLIAM F. NORRIS, of Philadelphia.

The first paper read was

AN ANALYSIS OF NINETY CASES OF SIMPLE CHRONIC GLAUCOMA, WITH SPECIAL REFERENCE TO THE EFFECTS OF IRIDECTOMY UPON THE ACUITY OF VISION AND THE VISUAL FIELD,

by DR. CHARLES STEADMAN BULL, New York.

Detailed histories of the ninety cases were presented and the following conclusions formulated.

In endeavoring to draw some rational conclusions from the study of ninety cases, it seems wise to begin with a quotation from Priestly Smith, to whom ophthalmologists owe so much of their knowledge of the pathogeny and pathology of glaucoma.

(1) In considering the expediency of an operation in chronic glaucoma, he says, "In every case of chronic glaucoma, the responsibility of advising an operation is a heavy one, and should on no account be undertaken without a full explanation to the patient or his friends of the almost positive certainty of blindness on the one hand and of the uncertainties which beset the operation on the other. Having regard to the age of the patient, the impossibility of great benefit, and the possibility of a painful and accelerated progress, the prudent surgeon will only operate on the express desire of the patient to secure the only possible chance of benefit, however small it may be." Armed with the preceding precaution, it seems to be our duty to operate in cases of chronic progressive glaucoma, and the earlier the better.

(2) If the disease in a given case seems to be stationary and is still in the primary stage, and if it be

[2] Ziemssen's Cyclopædia, vol. vii, p. 236.

possible to test the vision and the visual field at short intervals, delay in operating is permissible; but a weak solution of eserine or pilocarpine should be used daily, merely as an aid in controlling the course of the disease. The examination of these patients should be at short intervals, and should invariably include tests for visual acuity and the careful examination of the visual field.

(3) If the disease exists in both eyes, but with useful vision in both eyes, the eye in which the disease is the more advanced should be operated on without delay; and the surgeon will be guided in his treatment of the fellow-eye by the result of the operation on the first eye.

(4) To insure the best result, the incision should be made well in the sclerotic, with a narrow cataract knife or a broad lance knife; and the entire iris, from one end of the incision to the other, should be carefully torn or excised from its insertion.

(5) The most carefully performed iridectomy by skilful hands is sometimes followed by rapid loss of what sight still remains, sometimes partial, but unfortunately, sometimes total.

(6) A successful result is, in the majority of cases, more likely to follow the operation if it is performed early in the course of the disease; but the maintenance of the existing degree of vision, even in these cases is not invariable.

(7) As regards the question of symmetry, it is probable that in the large majority of cases, probably as much as eighty per cent., the disease is sooner or later present in both eyes; and a careful study of the cases seems to establish the fact that there can be no specific interval of time which insures the second eye against an attack.

(8) If the patient is old and feeble, and one eye is still free from disease for a year or more after the other eye has become affected, it may be considered prudent to avoid an operation on the affected eye, as it is probable that the unaffected eye may remain free during the remainder of the patient's life.

(9) The condition of the field of vision is no constant guide either in forming a prognosis as to the progress of the disease or in deciding as to the time of operation.

(10) The acuity of vision bears no constant relation to either the success or failure of the operation.

(11) The anterior chamber is usually shallow, is occasionally entirely absent, but is often apparently normal in depth. The condition of the chamber gives no reliable hint as to the state of the vision or the visual field nor any indication as to prognosis.

(12) The appearance and motility of the iris appear to have some bearing upon the prognosis, though perhaps not to the extent believed by Nettleship. The latter states that in the cases in which the iris reacts rapidly to eserine the operation proves successful. This has not always been the experience of the reporter, but in the majority of the cases in which eserine caused rapid contraction of the pupil, the visual acuity was fairly good and the field was not seriously limited.

(13) The depth of the excavation in and the color of the optic disc seem to have no close connection with the defective vision or with the limitation of the visual field, nor did they offer any constant guide as to prognosis or to the effect of an operation upon the progress of the disease.

(14) The condition of the intra-ocular tension is a very uncertain guide in deciding the time for operating. It may be normal or increased or even diminished. It does not even seem to bear any constant relation to the degree of visual acuity or to the state of the visual field. The steady maintenance of the increased tension, however, without any diminution, almost invariably indicates the necessity for an immediate operation, and this necessity is as especially indicated if the tension is continually on the increase.

(15) The health and age of the patient exert a decided influence upon the effect of the operation. Any marked evidence of senility is distinctly unfavorable to operation.

DISCUSSION.

DR. H. KNAPP, New York: During the past 19 years I have operated on 670 cases of glaucoma, 226 of which were cases of chronic glaucoma. I think that the prognosis may be a little more favorable than has been indicated by Dr. Bull. I have had four cases in which maglignant disease followed operation for chronic glaucoma. I do not agree with the author as to the advisability of the continued use of pilocarpine or eserine in those chronic cases where operation seems doubtful. I advise its use when there are recurrent symptoms. In prognosis I am guided a great deal by the condition of the iris. My operations have been done with the lance-shaped knife. I consider it of great importance to carefully reduce the edges of the coloboma, not only by external pressure but also by the use of the blunt probe. I am also careful not to make the operation too peripheric. Peripheric wounds are more liable to cystoid scars.

IRIDECTOMY IN GLAUCOMA,

by DR. EMIL GRUENING, New York.

The speaker classified the different forms of glaucoma under the following heads: (1) acute inflammatory; (2) chronic inflammatory without visible degenerative changes in the iris; (3) chronic inflammatory glaucoma with visible degenerative changes in the iris; (4) simple glaucoma; (5) intermittent glaucoma, and described cases illustrative of these different varieties.

DISCUSSION.

DR. S. O. RICHEY, Washington: I do not believe simple chronic glaucoma to be entirely a local affection. I think that it is a local expression of a cause to be looked for in the nervous system. I have used eserine with satisfaction in the early stages, but support it by galvanism applied to the cervical ganglia. In some cases this will enable us to avoid operation.

DR. SAMUEL THEOBOLD, Baltimore: I have met with one case in which an attack of pronounced acute glaucoma was cut short by the use of eserine.

DR. C. S. BULL, New York: Eserine is frequently used in too strong solution. A solution of half a grain to the ounce may cause iritis after a single instillation. I never use a stronger solution than this. I often use one as weak as one-tenth of a grain to the ounce.

DR. B. ALEXANDER RANDALL, Philadelphia: I can confirm the remarks in regard to the value of weak solutions. In one case of severe absolute glaucoma a solution of one-eighth of a grain to the ounce was entirely successful in relieving the pain. It has been used steadily for three years with no recurrence of the severe symptoms, and without the intervention of any inflammatory trouble.

DR. S. D. RISLEY, Philadelphia: In experimenting with weak solutions of eserine, I have found that a distinct effect was experienced from a solution as weak as one-thirtieth of a grain to the ounce. If this was applied three times a day, it would in two days cause distinct brow-ache. I have seen benefit from weak solutions where stronger solutions failed to give relief.

DR. HENRY D. NOYES, New York: One point to which my attention was called many years ago is that in certain instances of evident glaucoma with a large amount of refractive error, it has seemed that the aggravation of the glaucomatous disease has been dependent upon the accommodative strain. In operating I have gradually withdrawn from the extremely peripheral place of incision. I prefer to come closer to the border of the cornea than some do. This involves less risk and is easier of performance.

DR. SAMUEL THEOBALD, Baltimore: My experience tends to convince one that astigmatism and particularly astigmatism against the rule, is frequently the cause of glaucoma.

DR. ARTHUR MATTHEWSON, Brooklyn: In one case of glaucoma in which iridectomy had been done without arresting the progress of the disease a large ingestion of strychnia caused a decided improvement of vision, which continued. I have used it in other cases with good effect.

THE USE OF THE CURETTE IN ANTERIOR TRACHOMA,

by DR. EMIL GRUENING, New York.

The speaker after referring to the various measures proposed for the relief of this condition, described an operation which he had employed in eleven eyes during the past two years. A six-per-cent. solution of cocaine was first instilled. The surface of the cornea and the vessels present were then scraped away with a gouge-shaped instrument and the vessels followed well on to the conjunctiva. The eye is then washed with boric-acid solution and warm compresses applied for four or five days. In three cases new vessels formed and the operation was repeated. The ultimate result in all the cases was highly satisfactory. In old and protracted pannus this operation may be recommended for its directness, simplicity and efficacy.

DISCUSSION.

DR. S. D. ST. JOHN, Hartford: I have used this operation in one case with the highly gratifying result of increasing the vision from $\frac{4}{200}$ to $\frac{16}{200}$. This has since still further improved.

DR. H. F. HANSELL, of Philadelphia, read a paper on

CORNEAL ABSCESS,

describing its symptoms, and referring to the differential diagnosis between it and ulcer. He protested against the use of cocaine in abscess or other inflammatory conditions of the cornea. A few drops of strong solution will often destroy the epithelium. Instillation of eserine alternating atropine was recommended. Operative interference should be limited to the evacuation of the pus.

FURTHER OBSERVATIONS ON MALARIAL KERATITIS,

by DR. CHARLES J. KIPP, Newark.

The author had called attention to this condition in a paper read before the Society in 1880. He had seen one hundred and twenty cases of the disease. In all there had been paroxysms of malarial fever and in ninety per cent. the corneal inflammation followed a few days after a paroxysm. In twenty-five per cent. the patients had suffered from similar trouble in previous attacks of malaria. The inflammation of the cornea occurred in the form of serpiginous ulceration, with narrow prolongations. The trouble began as a line of small grayish elevations, which soon broke down forming a furrow of ulceration. In mild cases the duration is two or three days, while in severe cases it may last several months. There is a marked tendency to recurrence in subsequent attacks of malarial fever. In a few cases he had seen a similar affection in non-malarial individuals. The treatment consists in remedies directed to the general condition and in mild cases with warm fomentations. In severe cases a one-per-cent. or two-per-cent. solution of nitrate of silver applied directly to the furrows after the use of cocaine answers well. In some very severe cases the actual cautery was employed. This arrested the progress of the disease and stopped the pain, provided the malarial trouble had previously been cured.

DISCUSSION.

DR. HENRY D. NOYES, New York: During the past fifteen or twenty years, I have met with cases of superficial keratitis due to malaria. It is rare to find the deeper tissues invaded. I am led to suspect a malarial origin in cases where there is exaggerated tenderness of the supra-orbital nerve and distinct anæsthesia of the surface of the cornea. The form of ulcerative keratitis which has been described I regard as of mycotic origin and have cured it by scraping thoroughly the lines of infiltration.

DR. T. Y. SUTPHEN, Newark: I have seen cases similar to those described by Dr. Kipp in patients suffering with malaria and where there has been no distinct chill; the individuals have resided in malarious districts.

DR. JOHN GREEN, St. Louis: I have seen many cases in which malarial fever was followed by superficial keratitis or keratitis modified by neglect or improper treatment. I have not met with the form described by Dr. Kipp.

DR. EMIL GRUENING, New York: I have seen this form of ulcerative keratitis but I have associated it with the teeth. These patients have had tartar on the teeth and have been in the habit of moistening the lips with saliva. I think, therefore, that the source of infection is in the mouth.

DR. SAMUEL THEOBALD, Baltimore: I have also seen for many years this keratitis associated with malarial trouble. These cases do not always show ulceration of the cornea. I have in a general way regarded this condition as analogous to herpes zoster. I have once or twice seen iritis associated with the keratitis following malaria. In one case of malaria I have seen this keratitis with herpes zoster of the temple.

IRRIGATION OF THE ANTERIOR CHAMBER,

by DR. J. A. LIPPINCOTT, Pittsburgh.

This procedure is useful for the removal of débris in cataract extraction and of clotted or liquid blood. In order to accomplish this successfully it is necessary to have an apparatus which can be readily made and kept aseptic; which will always be ready for use; which can be easily handled and the movement con-

trolled with one hand; whose ejecting force is capable of being easily regulated; and which is free from liability of forcing air bubbles into the anterior chamber. As fulfilling these requirements he exhibited an apparatus consisting of a small metal receptacle with which was connected a rubber tube ending in a metal nozzle, the flow of liquid being controlled by a short piston in a rubber handle through which the rubber tube passed. The ejecting force can be varied by elevating or lowering the receptacle.

DR. GRUENING, of New York, exhibited a small flask devised by von Graefe for the same purpose.

DR. DAVID WEBSTER, of New York, exhibited

TWO SPECIMENS OF SWORDFISHES' EYES.

DR. HENRY D. NOYES, New York, exhibited a

SPECTACLE FRAME

in which the nose-piece of the eye-glass was combined with the ordinary spectacle frame.

ENUCLEATION OF THE EYE IN PAN-OPHTHALMITIS,

by DR. HENRY D. NOYES, New York.

There has been reported by various observers thirty or forty deaths following enucleation, almost all from meningitis, about one-half of the fatal cases have occurred after enucleation during acute suppurative pan-ophthalmitis. At the New York Eye and Ear Infirmary there has been no deaths from this cause, when no additional operation in the orbit, such as the removal of tumors, etc., have been done. The number of enucleations, from 1868 to 1888, was 1,164; the number of eviscerations, 17. Pan-ophthalmitis existed is 14 per cent. of the cases. It seems fair to conclude that while a small risk to life is incurred by enucleation of the eye, the supposed increased risk by the existence of suppurative pan-ophthalmitis as not so far justified by the facts as to bar its performance in this condition.

(To be continued.)

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

PHILIP COOMBS KNAPP, M.D., SECRETARY.

JANUARY 17, 1889, DR. COWLES in the chair.

DR. J. B. AYER read a paper on

CEREBRAL SYMPTOMS, CONNECTED WITH PHTHISIS.[1]

DR. H. R. STEDMAN said that the paper was an interesting study of the affinities between tuberculosis and mental disturbance, as viewed from the standpoint of the tubercular symptoms. The affinity was particularly marked in heredity. Cases of hereditary insanity were often seen in phthisical families. In children the mental trouble was more likely to be delirium.

DR. BOLAND thought the mental trouble rather a coincidence, from anæmia, œdema, etc., as we see it in cardiac disease.

DR. FISHER said that the relation of phthisis and insanity was important, and most writers think it an intimate one from an hereditary point of view. Phthisis usually has the effect of producing nervous diseases and insanity in the second generation. Phthisical insanity was a term used by several writers, especially Skae; but most of Skae's terms were convenient clinically, though incorrect scientifically. He had used the term himself, applying it to cases where advanced phthisis was the sole discoverable cause of the mental condition. The only characteristic is a prolonged and rather active delirium, with or without hallucinations. The condition varies with the physical health. A boy of seventeen, with a phthisical heredity and tuberculosis of both lungs, emaciated, and in a hopeless condition, became so excited and actively delirious as to be sent to the Boston Lunatic Hospital. He had various relapses; but as his physical condition improved, his mental trouble got well. Fatigue, would however, bring on a relapse. Another patient, who had some joint disease and phthisis, had two attacks of delirium before her death. Both had hallucinations of sight and hearing. For such cases phthisical insanity was not a bad term.

DR. MOULTON said that many cases of insanity had a phthisical heredity. It is an important element in causation, and it is not to be lost sight of in prevention. He used the term, which seemed as good as any for certain cases. Many insane patients develop phthisis, which is attended with a clearing up of their mental symptoms.

DR. E. P. ELLIOT thought it impossible to rely much on asylum statistics, for a diagnosis from etiology is now out of fashion, and the etiology is always vague. Nevertheless, there was much phthisis in the asylums. There were two sorts of cases: one, where phthisis is developed in the chronic insane, the insanity not being modified by phthisis; the other, where mental trouble comes on after phthisis. There is some similarity between them. Delirium is not common, but they are often chronic cases of vague and not well-systematized delusions of persecution. These are usually termed phthisical insanity. It is useless to set this apart, as it is not confined to phthisis, but it is seen in any patient with debilitating disease, cancer, cirrhosis, or alcoholism.

DR. COWLES said that phthisical insanity always seemed a faulty term, showing the unsatisfactory nature of the etiology of insanity. If there is a direct etiological relation between phthisis and insanity, why is there so little insanity with so much phthisis? There are two forms in which the etiology is traced. One by heredity, which is not direct. Phthisical parents have defective offspring, but they are not always insane. Phthisical persons have a weak and unstable heredity. Such cases are prone to mental disturbance with physical debility, which gives a reason for the association of insanity with phthisis. Being defective, the patient has phthisis. We ought to see more insanity among the phthisical than we do. Phthisis and insanity in a single person shows the unsatisfactory character of the etiology of all forms of insanity. If there were a relation, it ought to be in a characteristic form. Insanity, on the whole, is of an asthenic type. There were only two cases at the McLean Asylum. One lady with advanced phthisis, was melancholy, depressed, tearful, agitated and slightly suicidal. She had an exacerbation of the phthisis with fever, and in it got better mentally. At first there was a poor brain nutrition, but the fever caused cerebral congestion, and thus improved the nutrition. Another lady with mild melancholia and phthisis, grew worse, had hectic, and got better mentally. Toward the close she showed considerable mental activity, painted in water-colors and had the spes phthisica. It was hardly correct to use the term phthisical insanity, except to show that

[1] See page 128 of the Journal.

phthisis co-exists, for there is so much phthisis and so little insanity.

DR. AYER said that his percentage of mental disturbances was large as compared with ordinary experience. That was perhaps because at the Channing Home the patients were constantly associated with the matron and the attendants, and there was an excellent opportunity to study slight mental changes.

NEW HAMPSHIRE MEDICAL SOCIETY.

REPORT of the Ninety-ninth Annual Session held at Concord, N. H., June 17 and 18, 1889.

DR. A. P. CHESLEY, of Concord, read a paper on

PHYSICAL CULTURE.

DR. M. W. RUSSELL, of Concord, made a

REPORT ON SURGERY.

After giving three cases of punctured wounds, where the general treatment was free incision to the bottom of the wound, and tobacco and flaxseed poultices applied to the wound, he said: The members of this Society who attended the lectures of the late Dr. Dixi Crosby will remember the importance which he attached to freely incising to the bottom all punctured wounds, in order to prevent tetanus. He claimed excellent results from this mode of treatment. In treating these cases, I introduce the knife a little to one side of the wound and carry it as deep or a little deeper than the instrument penetrated, and then cut outwards freely. I should do this even at the risk of dividing the plantar or palmar arch, if the injury was in the neighborhood of these vessels; as I firmly believe that the advantages of the operation infinitely outweigh the damages of this accident. I have great confidence in the tobacco poultice in these cases. It seems to act as a sedative, removing the irritation of the peripheral nerves.

Another case, of "a slight injury to the distal extremity of the finger of a healthy person," was followed at the end of twenty-four hours by pain and by tonic contraction of all the fingers of the injured hand. Pain more or less severe, and swelling of the hand, were symptoms which characterized the next four days; but there was so little inflammation at the seat of the injury that a free incision healed firmly by first intention. On the fifth and sixth days the pain was much less, and the swelling diminished? Then, suddenly, without apparent cause, the pain became intense, and mortification ensued within fourteen hours. What produced the obstruction to the arterial circulation which resulted in gangrene? In what way did the slight wound of the distal end of the finger cause suppuration in the hand? Were all the symptoms the result of injury to a nerve?

A male patient was admitted to the hospital January 21, 1889. About three weeks previous to his admission he was struck upon the dorsal aspect of the ring finger of the left hand by the sharp edge of a hatchet, which inflicted a flesh wound only. This was followed by inflammation and extensive swelling, and later by suppuration in the hand and finger. Previous to his admission, the back of the hand had been freely incised, and pus had discharged freely. At the time of his admission a large pocket of pus in the palm of his hand was opened. At this time the original wound was not healed, and its edges were swollen, excited and ragged. The whole hand was badly swollen and had an erysipelatous blush. January 23d, the finger was amputated at the metacarpo-phalangeal articulation. The first phalanx was entirely denuded of periosteum, and so softened as to easily break in pieces. The bone gave no evidence that it was injured by the blow. After the operation the swelling subsided rapidly, but suppuration kept up for two weeks. The wound healed as readily as could be expected, and the patient was discharged well, February 10, 1889. This patient was a robust and apparently healthy man, and the wound was comparatively a small one made by a sharp instrument. It was such a wound as we should expect to heal fully in a week. Instead of this, necrosis of the bone set in and abscess of the hand resulted.

The importance of the early removal of cancerous growths is now acknowleged by a larger part of the medical profession. It is most probable, if the fact has not been positively demonstrated, that the spread of the disease to other parts and the formation of accessory foci is due to the carrying of granules detached from the parent cell to surrounding or even distant tissues. I believe that all tumors, the nature of which is at all in doubt, should be removed at once, if they are in a position which permits their removal, and further that the operation should be thorough and radical. I think it is a fact that tumors which are at the beginning free from any taint of malignancy, may at a later period become the seat of a malignant growth. It is not consistent with our knowledge of carcinoma to suppose that these growths are cancerous at the beginning. It is much more probable that they furnish a structure peculiarly adapted to the development of cancerous tissue. It is an important question whether the early removal of these tumors might not have prevented entirely the development of cancer in the patient.

DR. J. J. BERRY, of Portsmouth: The method of treating punctured wounds, as described in the paper, I should consider a very effective and proper one. If I had reason to believe, in a given case, that the wound contained septic or other foreign material, or that much internal laceration existed, I should follow the methods advocated in this paper. In other cases, however, I should feel inclined to wait a little before enlarging the wound and increasing the area of granulating surface.

DR. G. P. CONN, of Concord, read a paper on the

DISPOSAL OF GARBAGE.

The disposal of garbage in our small towns and cities is not a question of special importance, but in populous places the problem of what shall be done with the waste from the household is found to be of importance second to none other. Fortunately, in New Hampshire we have but few towns and cities so populous or so crowded as to require the attention given to places reckoning their population by hundreds of thousands. But the crowding of our summer hotels and camp-grounds, unless properly guarded and protected against unsanitary conditions, cannot but become a source of unhealthfulness, probably of infectious disease; and it is to this that I desire to call the attention of the physician. Many of these places have fairly outgrown the expectations of their projectors, and therefore little or no thought has been taken of what to do with the drainage, garbage or waste products, and at none of

them has there been any adequate provision made for the disposal of the waste and garbage incident to such crowds.

It is apparent that this problem is growing year after year in New Hampshire; and, as all of us have under our care families who spend days, weeks or months at such resorts, we should warn them of the care necessary to protect their health.

I would be glad if I could bring before you some definite plan that would be inexpensive, but entirely satisfactory in its manner of dealing with the disposal of garbage and other waste matter. But while experts are examining into the merits of various methods, no one has, as yet, solved the problem.

To the profession is granted the high privilege of being teacher and adviser, and our power for good and for evil is very extensive. In matters like this, whenever the public seriously demand reform, the work is, in some way, accomplished. When the people of a town or city are a unit upon any question there is no trouble in bringing about the necessary means to complete the work. So it will be in the future disposal of garbage; and it behooves the profession to be leaders in public opinion, rather than to follow in the wake of others. We should encourage the public in making the best use of our present means and to hope for something better within a reasonable period.

DR. CHILD: I understand that near Boston there has been a furnace built, and men go round and gather up every piece of pie, scrap of biscuit, crust of bread, etc., and put it into this furnace and thoroughly dry it. I do not know the exact process, but we can readily imagine it. After being thoroughly dried, it is placed in flour barrels and sent into the country for hens' food, etc. It makes a perfectly healthy food, so far as I can see. I believe this will be one way of disposing of garbage.

DR. ROBERT BURNS, of Plymouth, read a paper on

THE USE OF ANTISEPTICS BY COUNTRY SURGEONS.

The surgeon of the city, with all his expensive appliances and machinery and skilled assistance, may find the aseptic method of treating wounds practicable; but the country practitioner, who must forego those aids, and who finds his patients oftentimes in anything but aseptic surroundings, must resort to other and simpler methods.

All my surgical instruments and dressings are carried in one small hand-bag. I have carbolic acid, tablets of corrosive sublimate and iodoform. Needles, knife-blades and other small instruments are kept in a 1 : 60 carbolic-glycerine solution. After using and cleansing, they are put back into this solution, and thus are always ready for immediate use. Other large instruments are put into a 1 : 40 carbolic solution some time before needing them. My bag contains silk on a reel, and drainage-tubing, both in a 1 : 4000 solution of corrosive sublimate. Sterilized sponges are carried in a 1 : 1000 corrosive-sublimate solution, and suitable pieces of oiled silk are put in the same, some time before using.

After the flesh adjacent to the wound has been thoroughly washed, both skin and raw surface are bathed in a corrosive-sublimate solution, the strength varying between 1 : 1000 and 1 : 5000, in inverse proportion to the extent of the raw surface. After the incisions are completed, the cut surfaces are washed for a considerable length of time in a 1 : 4000 corrosive-sublimate solution, hot enough to check bleeding, to blanch tissue, and to render the parts thoroughly aseptic.

For ligature I use silk, and cut the ends short. If the wound is a large one and necessitates the use of a drainage-tube, I do not think that it makes much difference whether or no the ligatures are cut short. But if the wound be small, if there be no drainage-tube, or if it be early removed, I consider that the long ends of the ligatures prevent absolute healing in a short space of time. These short silk ligatures either become absorbed or encapsuled. They give me no trouble, and I get healing by first intention through the full extent of the wound, which is not closed until every particle of oozing blood has ceased. For healing, I depend largely on the most careful and accurate approximation of the parts.

After the wound is closed, and thoroughly washed with a 1 : 4000 corrosive solution, iodoform is used freely, as wounds seem to heal more kindly with it than without it. After this a piece of sterilized oiled silk large enough to cover the wound is applied. This is used for two purposes: to prevent the sticking of the dressings, and to keep the plasters which cannot be rendered aseptic from contact with the wound. Over this is placed several layers of sublimate or carbolic gauze, then a large piece of oiled silk to cover the whole, which is bandaged in the ordinary way. Subsequent dressings I do, if possible, myself, and make them as few and far between as may be. On redressing, the wound is generally found to be so clean that the usual washing is simply a process of dampening with an antiseptic solution.

Since I began the constant and systematic use of antiseptics, I have seen most cases heal without a drop of pus. In simple amputation I have come to expect healing by first intention, except around the drainage-tube, and solid healing by from twenty-one to twenty-eight days after operation. As a rule I greatly prefer the action of corrosive sublimate to that of carbolic acid as an antiseptic. But if I know of the existence of albuminuria, or suspect any latent tendency to disease or congestion of the kidneys I am very careful to avoid it.

It will be seen that my method is exceedingly simple, so simple that it would hardly be a matter of interest except for the fact that its very simplicity makes it practicable, and this especially adapts it to the unassisted country surgeon. It is now something over two years since I have seen a touch of surgical fever in my own practice, and in uncomplicated surgical cases, I have rarely seen a temperature above 100°. I now get healing of large cut surfaces by first intention as a rule, formerly it was the exception.

DR. W. B. PORTER, of Walpole, read a paper on

PNEUMONIA: ITS MORTALITY AND THERAPEUTICS.

For patients in the sthenic condition, the first remedy given by the highest German, French and American authorities is the use of cold-water compresses over the chest, or packing the whole body in cold packs. With patients of asthenic diatheses, I use hot-water compresses saturated with turpentine. In both classes of patients, if the tongue is coated, indicating some constitutional disturbance, I use mild aperients of some kind to act upon the hepatic and other secretory vessels. I often use a pill from Dr. Whitbeck's formula, as follows, with the very best results:

Podophyllin	1-4 grain.
Aloin	1-6 "
Capsicum	1-10 "
Nux vomica	1-10 "
Extract belladonna	1-10 "
Oleum tiglii	1-20 "

I give the pill once every three hours until the bowels move. If a periodicity occurs in the fever, I give a few grains of quinine at short intervals.

In our next visit, we find the second stage developing. The physical signs are all much worse, increased engorgement, vesicular murmur destroyed, loud and full bronchial respiration, mucus râles, crepitation, high temperature, rapid and tremulous pulse, respiration forty per minute, with dyspnœa and marked bilious complications. I resort to calomel. I lay out four or five powders from ten to fifteen grains, with five to ten grains of Dover or Tully powder, and order the nurse to give one every four hours. I repeat until I get the specific effect upon the liver and bowels.

At this stage, I change the wet compresses for counter irritation, then apply a warm poultice over the irritated surface, still using the febrifuge spoken of before, and in some cases, using aconite instead of digitalis, which might be unsafe to use on account of cardiac conditions. Mucilaginous drinks, together with expectorants, are required to moisten the tissues, and empty the bronchial cells of their purulent deposit. If the patient is suffering from prostration, stimulants and tonics are required.

I am not in favor of the use of antipyretics in large doses. I use them in small doses to quiet nervous excitement. In vigorous, full-blooded persons, with a temperature of 105°, pulse 120, lungs engorged, intense pain, great dyspnœa, threatened suffocation, I would open a vein in the arm or temporal artery, and should collateral œdema occur in portions of the lungs not congested, endangering life, I would bleed. Then if the pressure of blood caused brain symptoms, coma, and transient paralysis, I would use the lancet to prevent brain lesions and sudden death.

DR. THOS. HILAND, of Concord: I believe that less dosing and more taking care of your patient will give you a better result in pneumonia than to try to dose him every hour or two hours. No doubt Dr. Porter's cases do well under his treatment: but his cases do well or not in spite of a good deal of the treatment. I do not care who has charge of a patient of ten, fourteen, fifteen, or sixteen years of age, if you will give him half a chance, he will get well of ordinary pneumonia; but the old, the feeble, the young child, the person who has been on a debauch, these are apt to die; and there is no use in dosing them to death.

DR. M. C. LATHROP, of Dover: I have never in all my practice, heard of a case where bleeding has been resorted to in pneumonia. There may be cases where I should do it myself but I have never done it.

DR. WILLIAM CHILD, of New Hampton, read a paper on

THE USE AND ABUSE OF NARCOTICS AND ALCOHOLICS,

which was written in the humorous vein so characteristic of the author. In closing, he said: I have presented this theme to direct your attention to what we cannot ignore. We must aid in advancing these questions of reform, not by denunciation, intrigues, and harangues; but by a common-sense examination and discussion, holding to the proper use but restraining the abuse of any and all good gifts from the Creator. I am sure that a higher and better education will bring about the needed reform. I cannot see that we should demand the annihilation of narcotics and alcoholics.

DR. D. S. ADAMS, of Manchester: The medicinal use of alcohol, I fully believe in. We cannot come more fairly to a decision as to when to use it, than to look over "Pepper's System of Medicine." This is written by American authorities, and the general opinion therein contained would be the American idea. In looking over that work, I find that alcohol is recommended in twenty-nine different diseases only. I was a little surprised to find that in twenty-two of these diseases, it was recommended for almost the same symptom or condition of the system (depression of the heart's action).

DR. E. W. CUSHING, of Boston, addressed the Society on the subject of the

DIAGNOSIS OF PELVIC TUMORS.

Recent Literature.

An Elementary Treatise on Human Anatomy. By JOSEPH LEIDY, M.D., LL.D., etc. Second edition, rewritten, with four hundred and ninety-five Illustrations. Philadelphia: J. B. Lippincott Company. 1889.

This second edition of Professor Leidy's well-known work is to all intents and purposes a new book by the leader of American anatomists. The learned author implies in his preface that it is not meant to be of the same scope as the great English anatomies. It is an elementary treatise, and we gather that it is essentially a report of Dr. Leidy's course at the University of Pennsylvania. This surmise adds greatly to the interest with which we review the book. From the fact that the treatise is an elementary one, it follows that many matters of detail must be omitted, and to omit judiciously is one of the most important attributes of a teacher. We find also that the author has departed from the usual order of presenting the different divisions of the subject, and that he has accepted some modifications of the established nomenclature.

As to the order of the work, the microscopic anatomy is scattered throughout the book in a way that mars the unity of treatment of that branch. Thus the minute structure of bone comes at the beginning, while that of cartilage comes with the so-called connective tissues, just before the muscular system. Surely bone is in structure one of this group, and should not be artificially separated from the rest. Many of the illustrations of the tissues are decidedly diagrammatic, and rather suggestive of black-board sketches. We think the author has shown good judgment in the amount of space given to histology. He has given what is absolutely essential for a course of lectures on anatomy, and, from this point of view, we praise omissions and summary descriptions which could not be permitted in a treatise on histology.

The bones and joints are taken together, an excellent plan in our opinion; then comes the muscular system; then the alimentary apparatus; which is followed by the vascular system; then comes the other

viscera; and finally the nervous system and the organs of special sense. There are obvious reasons why the method of English anatomists in putting the vessels and nerves before the viscera should be abandoned. It is, to say the least, unsatisfactory to describe the arteries of the duodenum to students still in happy ignorance of the shape and position of that difficult organ. Therefore, we see good reasons why the alimentary apparatus should precede the vessels and nerves, but we do not see why all the other viscera should not do so likewise.

The descriptions of the bones are strong, clear and concise, not overburdened with details. In some of the bones of the skull, especially the temporal, the author allows himself freer play, and the result is admirable. The account of the sphenoidal spongy bones is the only one we call to mind which is at once comprehensive and clear. We regret that we cannot speak with equal praise, or indeed with praise at all, of the treatment of the joints. It is wanting both in accuracy and in thoroughness. To define rotation as "the motion made by a bone when it rolls on its axis" and to add, for an illustration, "as in the movements of the radius upon the ulna," is misleading. The following account of the movements of the ribs is most unsatisfactory: "The chief movement of the thorax, as in breathing, consists in partial rotation of the ribs on their axis, up and down, where they articulate with the vertebræ, facilitated by somewhat similar motion in the costo-sternal articulations. In the movement, the ribs are alternately raised and depressed from their fore part." We doubt if the student will understand what is meant by the axis of the rib, and would submit, moreover, that the motion of the longer ribs on an anterio-posterior axis is a secondary factor of importance, to say nothing of the free movement of the last two ribs. We are told that, "in the ordinary opening and closing of the mouth, the condyles of the lower jaw rotate on their long axis within the glenoid fossa." One has only to put one's finger on the head of the jaw, and open the mouth, to find that the former moves forward and downward; but it would stay in place if it rotated on its axis.

The section devoted to muscles is very good, though now and then we wish that a little more had been said of their actions. This is the natural place to discuss the changes in nomenclature which Professor Leidy had adopted, for these changes are more striking in the muscular system than elsewhere. As he states in the preface, he has not attempted a radical change, which he justly believes would be more confusing than profitable, but has tried to use simple names, and to change them as far as possible into English. We think he has been very successful; but we believe he would have been still more so had he used out-and-out English words instead of hybrid Latin and English composites. As an example, he has simplified the *extensor ossis metacarpi pollicis*, the *extensor primi internodii pollicis* and *the extensor secundi internodii pollicis* into the "first, second and third pollical extensors" respectively, which is a decided gain; but we submit that it would have been far better to have called them the "first, second and third extensors of the thumb." The *peroneus longus* becomes the "long peroneal," but by a strange inconsistency the *tibialis anticus* is the "anterior tibialis," instead of the "anterior tibial." Worst of all, is the "terete," which had much better have been the "round" pronator. These blemishes appear to be owing to the author not having sufficiently adhered to the wise plan he had proposed. A change which seems to us unfortunate is to turn the *lobus Spigelii* of the liver into the "caudate lobe," as the latter term is usually applied to what is here called the isthmus.

We must pass on more rapidly. We are glad to find the muscles of the tongue, the palate and the eye described in connection with these organs. The vascular system calls for no special notice. The treatment of the brain is very satisfactory. The veteran teacher of anatomy has shown the result of his experience in giving just enough, and in given it well. The same may be said of the chapters on the organs of sense.

The illustrations are of varying merit, but in the main hardly as good as the book deserves. The bones of the carpus and tarsus, as well as the ossicles of the ear, should be larger, and the same may be said of the illustrations of the convolutions, which would gain much by greater size. We must remark, by the way, that it is to be regretted that one of the brains chosen to show the convolutions should present decidedly uncommon features.

The book, in spite of some shortcomings, is an admirable one for the purpose the distinguished author had in view. It is, to be sure, less complete than the ambitious and interested student would wish, but it is just the thing for the great mass of students. It is clear; it is, with some exceptions, sufficiently accurate; and it is of convenient size, with good type and paper.

T. D.

Φυσιολογικαὶ Πραγματεῖαι ὑπὸ τοῦ τῆς συνόλου ἰατρικῆς διδάκτορος ἐπιτίμου ταύτης καθηγητοῦ διαφορῶν ἐπιστημόνων τε καὶ φιλολόγων, ἑταίρων τε καὶ συλλόγων ἡμεδαπῶν τε καὶ ἀλλοδαπῶν ἐπιτίμου μέλους ἢ προέδρου, της ἄυτου Α. μεγαλειότητος τοῦ Σουλτάνου ἀρχιάτρου, κ. τ. λ. Σπυρίδωνος τοῦ Μαυρογενους.

Εν Παρισιοις, ἐκ τῆς τυπογραφιας, "ο ἀστὴρ."

The universality of medical and physiological science receives a new exemplification when we take up a book like this, founded on researches of French and German physiologists, written by a Turk, published in the Greek language, and printed at Paris. The volume in hand is one of over 317 pages, and is written by Dr. Maurogenos, (a name which seems from its composition to imply a still furthur extension of the cosmopolitan make-up, already referred to in the book), the physician-in-chief to the Sultan. It treats of several subjects: first, of the differences between the sexes, as to size, the appearance of the tissues and the blood, the strength, development and longevity, the performance of functions, mental activity, etc. The closing sentence only of this section reveals an occidental conservatism and a mournful lack of responsiveness to the social advancement of the western world, when he says, with a warm exclamation, Πρὸς Διός! "let men be men and women be women!" A section on life and soul, and their relations to each other follows with considerations of a physiological and psychological nature, and the last half of the book is occupied with observations upon sleep, wakefulness, and on the phenomena of sleep, dreams, somnambulism, etc.

— The tooth-pick mills of Maine have mostly shut down, says the *Druggist Circular*, on account of overproduction and inability to dispose of their stock. An important outlet for the lumber product seems to be thus cut off.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 8, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,

THE UNICITY OF BRIGHT'S DISEASE.[1] — II.

IN 1870, Klebs of Prague, showed that in scarlatinous nephritis the lesions begin and predominate in the Malpighian glomerules. This notion being seized upon and given extension by other pathologists, the conception became gradually formulated, and is coming to be more and more verified, that glomerulitis is the initial lesion of all the nephrites with albuminuria, whatever may be the infectious, toxic, or other cause of these nephrites. The unicist doctrine of Bright's disease is based on this notion.

In 1879, appeared the important memoir of Bamberger.[2] According to his researches, the microscope always shows an interstitial hyperplasia in connection with the parenchymatous inflammation of the tubuli. The connective tissue hyperplasia is not, it is true, generalized, as in the small red kidney, but localized in spots here and there, with thickening of the interstitial tissue and multiplication of the nuclei. Bamberger does not believe that pathological histology justifies the distinction between the large white kidney and the small red kidney. Klebs had shown that an interstitial glomerulitis, with round-cell proliferation and obliteration of the vascular tuft, is the starting-point of lesions which end finally in parenchymatous degeneration. Bamberger's histological researches and his clinical observations point to the same conclusions: the two distinct types of the disease may exist, but mixed forms are frequent in all degrees, and are often accompanied with amyloid degeneration. He has seen cases where the symptoms — insidious onset, frequent micturition, etc. — had led him to diagnosticate during life a granular kidney, and where the autopsy revealed the lesions of chronic parenchymatous nephritis. Again, he had seen other cases whose history and whose course were those of parenchymatous nephritis, yet the patient lived many years, and the autopsy showed the small contracted kidney.

From Bamberger's experience, then, it would appear that no more than histology, can clinical observation enable one absolutely to distinguish the two forms, the one from the other, and the small red kidney might well be what Bright and Frerichs thought it was — the last term of a process not differing essentially from that which leads to the formation of a tubular or parenchymatous nephritis.

Weigert's valuable memoir on Bright's disease also appeared in 1879.[3] The capital point which he endeavors to enforce is that it is impossible to maintain the histological differences which characterize the traditional scheme of the large white kidney and the small red kidney. It is a mistake to say that in the large white kidney the tubuli are alone altered, that there is no connective tissue proliferation, or that, if this exists, it is accessory and little marked. It is a mistake to assert that in interstitial nephritis, the intertubular spaces, enlarged and infiltrated with nuclei, circumscribe normal epitheliums. As well in the contracted kidney as in the white kidney, the alterations pertain both to the canaliculi and to the connective tissue. Even in the acute forms, the accumulation of round cells in the intertubular spaces, in masses more or less extensive, and the atrophy in places of the canaliculi, are the rule. The lighter the renal affection, the less marked are these interstitial lesions; the more violent the inflammation, the more extensive the connective tissue proliferation. In the chronic forms of the large white kidney, not only are masses of embryonal cells met with in the interstitial tissues, as many writers have noticed, but there is organization and thickening. Bowman's capsules are transformed into fibroid tissue, and their glomeruli have undergone different degrees of degeneration, and the arteries have suffered degenerative changes. The differences then, which the kidneys in Bright's disease present, from the large white kidney to the small red kidney, have nothing about them which is essential; it is only a question of degree. It is the acuteness, the extent, the profundity of the alterations rather than their histological characters in themselves, which create the variable aspects of the organs. The existence of amyloid degeneration changes nothing as to the nature of the process, which is that of an inflammation with tendency toward atrophy. Nor do the lesions differ more in the small white kidney and the small red kidney. If, as has been said, the granulations are larger in the former, it is because there is more normal tissue left, and the atrophy is less pronounced. The small red kidney represents only a more advanced degree of the atrophic process than the small white kidney.

If the lesions are the same, why the difference of coloration between the white and red kidneys? Weigert attributes the yellowish white color of the kidneys to fatty degeneration of the epitheliums and the more or less general anæmia of the organ. The steatosis is due either to the poison itself which has

[1] Continued from page 96 of the Journal.

[2] Volkmann's Sammlung Klin. Vorträge, 1879, p. 1533. We have in this exposition closely followed the admirable summary of Lecorché and Talamon (Traité d'Albuminurie, etc.).

[3] Weigert. Volkmann's Sammlung, 1879, Nos. 162, 163. We have followed the citations of Lecorché and Talamon.

caused the nephritis, and which acts directly on the cell, or to the insufficient afflux of oxygen or of blood necessary for the nutrition of the epithelium, by reason of the impairment of the local circulation. As for this impairment of the circulation, it depends on local and general causes. The local causes are the alterations of the walls of the blood-vessels (as in amyloid infiltration), the destruction of the glomeruli, the accumulation of cells in the intertubular tissue, lastly, the interstitial œdema, inflammatory or dropsical, which gives to the cortical substance of the large white kidney a sort of aqueous consistency.

To these local conditions, which unite to impede and slow the blood current so as to render the kidney almost exsanguinated, is added a more general cause — the lowering of the arterial tension, and the failure of the heart to undergo hypertrophy. In the chronic forms with extremely slow evolution, where the heart has time to hypertrophy, this hypertrophy compensates the effects of the local impediments which oppose the capillary circulation, and remedies the renal anæmia; whence the red coloration of the small atrophied kidney. According to Weigert, then, the small white kidney is distinguished from the small red kidney, solely by the anæmia which accompanies the interstitial inflammatory process. When the local circulatory troubles are but little pronounced, and develop slowly, it is the small red kidney which we observe.

As for the relations which exist between the epithelial lesions and the connective tissue proliferation, Weigert does not admit the notion of a primary interstitial inflammation compressing and producing atrophy of the canaliculi. The epithelium is the part first diseased; its atrophy or its destruction is the consequence of a nutrition insufficient by reason of the local impairment of the circulation, whether this impairment be due to alteration of the vessels of the glomeruli, to arterio-sclerosis, or to amyloid degeneration of the small arteries. This epithelial degeneration may exist alone for a longer or shorter time; but in virtue of this general law, which is as true for the kidneys as for all other organs, to wit: that *wherever the epithelium or the parenchyma of an organ is destroyed, connective tissue tends to take the place of the elements which have perished,* it is not long before nuclei and round connective tissue-cells make their appearance around the altered canaliculi, and the process completes itself in the progressive substitution of this tissue of new formation for the elements of the parenchyma destroyed.

To sum up, according to the unicist view: Histologically there are no essential differences between the small red kidney and the large mottled or white kidney. The partisans of dualism overlook the intermediate forms, the large red kidney and the small, white granular kidney. Weigert does not pretend that the large white kidney may be transformed into the small red kidney; he says only that between the two extreme forms there exist mixed forms presenting anatomical characters common to both types, and resembling more or less the one or the other type. The distinction between the two forms is an affair of degree and not of species, and when one attempts to trace a definite boundary line between them, this is found to be impossible.

Lecorché and Talamon believe that we must look to etiology for an explanation of the diversity of evolution of the disease and its ever-changing aspects, the agencies provocative of Bright's disease being multiple. They ask: "what rôle have these agents in the development of the renal lesions? Have they a special influence on the direction of the histological process, and do they suffice to explain the deviations?" Here the appeal is made to experimentation, which shows "that whatever may be the cause of the albuminuria, the primary and fundamental lesion is always an alteration of the glomeruli. Rapidly, moreover, and sometimes simultaneously, the other elements of the kidney undergo alteration: blood-vessels, connective tissue, and tubular cells," in short, the interstitial inflammation is always secondary to the epithelial lesions. This, at least, is the result of an investigation of all nephrites of experimental (toxic) origin; and pathological causes, it is believed, cannot act differently from agents of experimentation from the point of view of their primary action. Both classes of causes lead to one of two evolutive varieties of lesions: either the glomerulo-tubulitis is rapid, acute, more or less generalized, or it is slow, chronic, more or less limited. The type of the first variety is the glomerulo-nephritis produced by cantharides-poisoning in large doses; the type of the second is the nephritis consecutive to lead-poisoning in small long-continued doses.

The large white kidney and the small white kidney are nephrites arrested in their evolution, the one at a period quite near its onset, the other at a much later period. Neither the generalized fatty degeneration of the white kidneys, nor the amyloid infiltration of the arteries (causes of the anæmia and the pale color of these organs) are the direct consequences of the primary process of which the kidney is the seat; they are lesions superadded, and this addition is in etiological relation with the general state of the subject in whom the nephritis is developed. It has for its result — in producing a rapid and general disorganization of the renal filter, incompatible with life — an arrest of the natural evolution of the nephritis, and as it is not a consequence of this evolution but a complication, it may surprise the kidney at all periods of its atrophic inflammation. This is why we may find at the autopsy, white kidneys of all dimensions.

The more natural and uninterrupted the evolution, the more the secondary and final lesions of connective tissue sclerosis predominate.

THE DEATH PENALTY BY ELECTRICITY.

Mr. W. Bourke Cockran, counsel for William Hemmler, who some time since was condemned to death by electricity, in accordance with the provisions of the new law regulating capital punishment in New

York, has raised the objection that the law is unconstitutional, in that the constitution of the State expressly provides that no criminal shall be put to death by means that are "cruel or unusual." Judge Day, of Cayuga County, before whom the argument was made, appointed Mr. Tracy C. Becker, a Buffalo lawyer, as referee to take testimony in the case, and a large number of witnesses including Drs. Alfred L. Loomis and A. D. Rockwell, and Thomas Edison have been examined, while additional experiments have also been made at Mr. Edison's works at Menlo Park. A great deal of conflicting and not a little irrelevent testimony has been offered and received. No decision has as yet been reached in the case; but there is probably little real reason to doubt that a criminal can be deprived of life by means of electricity safely, quickly, and, if not agreeably, at least comfortably and humanely.

There seems to be an idea among the managers of electrical light and other electrical companies that it is not well to have the death penalty associated with electricity — just as some physicians object to its being associated with subcutaneous injections of morphia — and hence the tender zeal for Hemmler's legal rights.

MEDICAL NOTES.

— A "Congress of Hypnotism" is to be held in Paris, August 8th to 12th.

— Mrs. Mary E. Hanchett, who died recently at Chittenango, N. Y., is said to have been the second woman graduate of an American medical college. She received the degree of doctor of medicine from the Albany Medical College in 1848.

— The sixty-second meeting of German naturalists and physicians will be held at Heidelberg from September 17th to September 23d. One whole day will be devoted to excursions in the neighborhood, and on the evening of September 23d the Castle of Heidelberg will be brilliantly illuminated.

— A correspondent of the *Democrat* of New Orleans, writes that he has been treated for a bite of a mad dog at a Pasteur Institute in the city of Mexico. The institution in question is maintained by the Mexican government, and no charge is made for treatment.

— An attempt at blackmail was recently made against Mr. Malcolm Morris, of London, by a blackmailer named Grandy and a prostitute co-conspirator. They charged Mr. Morris with having, after immoral relations with the female prisoner, broken a promise of marriage made to her, but they were met by Mr. Morris handing them over to the police. It was then ascertained that this was not by any means the first speculation of this sort by the pair, and, notwithstanding the plea of their lawyer, that they had simply mistaken Mr. Morris for some other person, they were "sent up" for five years and eighteen months respectively.

— The *Philadelphia Inquirer* has been re-examining the character of the Schuylkill River, the source of Philadelphia's water-supply, and finds it to be very much contaminated almost all the way from the coal mines to the Fairmount Water Works. It describes it as a huge sewer draining an area inhabited by 250,000 people, before its waters are taken into pipes which supply 1,000,000 persons.

— Mr. Lawson Tait, in an article upon the "Pathological Importance of the Broad Ligament," in the current number of the *Edinburgh Medical Journal*, draws attention to a discovery which he has made which cannot fail to be read with interest in these days. In two churchyards in England; namely, at Romsey, in Hampshire, and at Bunhill Fields, in London, tombstones may be seen, each of which is inscribed with a note descriptive of a detail of treatment that had been adopted during the last illness of the person deceased. These women were presumably sufferers from cystic disease of the uterine adnexa. In the Romsey instance it is recorded that Mary Dawkins "fell asleep" in 1826, aged ninety, after having been tapped for dropsy forty-six times. In the Bunhill Fields case it is said that Dame Mary Page died in 1728, and that she was tapped sixty-six times in sixty-seven months, that two hundred and forty gallons of water were taken away, and that she never repined at her lot or ever feared the operation. Nothing could better show the difference between the treatment then and now than those mortuary clinical records.

— Tcheng-Ki-Tong, a high military mandarin, says the *London Medical Recorder*, has been edifying the world with some remarkable illustrations of the esteem in which native physicians are held in China. One of them having advertised that he had an infallible remedy for curvature of the spine, a hunchback applied to him and asked if he could straighten his back. The doctor undertook to do so, and placed the unfortunate patient on his back on a flat board. He then placed a similar board on his chest and abdomen and loaded it with heavy weights and stones. The result of this novel orthopedic surgery was that the patient was straightened out so effectually that he died on the spot. The quack claimed his fees on the ground that he had kept his promise; the bargain was that he should straighten his patient's back, but nothing had been said about his life! In China, it appears the distinction between physicians and surgeons is more sharply defined than with us, and every man is expected to stick to his own branch of the profession. A rich merchant was struck by an arrow which remained fixed in the wound. The principal surgeon of the place was sent for, and after insisting on pocketing his fee in advance cut off the projecting end of the arrow, leaving the point buried in the patient's body. On being asked to extract it, he said that medical etiquette would not allow him to trespass on a brother practitioner's province; the arrow being inside the body the case was clearly one for a physician! An old

Chinaman gave the following practical advice as to how to find the most eminent doctor in a strange place: "Count the number of ghosts crouching about the doctor's doorsteps; the one most in vogue has always the largest number."

— The Faculty of the College of Physicians and Surgeons of Baltimore held a meeting lately to fill the vacancies created by the deaths of Profs. John S. Lynch and Oscar J. Coskery and the retirement of Prof. A. B. Arnold, who has removed to San Francisco. Prof. Thos. S. Latimer was transferred to the chair of principles and practice of medicine and clinical medicine; Prof. Chas. F. Bevan to the chair of principles and practice of surgery, and clinical surgery; Prof. J. W. Chambers to the chair of operative and clinical surgery, and Prof. George H. Rohé to the chair of obstetrics and hygiene. Prof. Thos. Opie will continue as professor of diseases of women and dean of the faculty. To fill vacancies created by these transfers new professors were elected as follows: Prof. Henry Sewell, of the University of Michigan, to the professorship of physiology; Dr. George J. Preston to the professorship of anatomy, with the diseases of the nervous system as a clinical branch of instruction. Dr. N. G. Keirle was elected as lecturer on legal medicine, in addition to his demonstrations in pathology; Dr. George Thomas as lecturer on diseases of the throat and chest; Dr. G. A. Liebig, Jr., of Johns Hopkins University, lecturer on medical electricity, and Dr. J. H. Branham, demonstrator of anatomy. Drs. L. F. Ankrim, Frank C. Bressler and F. G. Moyer were appointed assistant demonstrators, and Dr. R. G. Davis, prosector of anatomy. Professor Sewell, who comes here from the University of Michigan, is an old Baltimorean, and was for several years demonstrator of biology in Johns Hopkins University. All the other appointees are residents of the city. As an evidence of esteem on the part of his colleagues, Professor Arnold was elected emeritus professor of clinical medicine on his retirement.

BOSTON AND NEW ENGLAND.

— A new cottage hospital is to be built at Quincy, Mass., similar in design to that already existing at Newton.

— The United States Hay Fever Association will hold its sixteenth Annual meeting on the 27th of August, at Bethlehem, N. H.

— Lawrence is to have a new hospital, $10,000 towards the necessary funds for the first building having been provided by Miss Helen C. Bradlee, of Boston, who had previously given $4,000 to the institution.

— "Naphtha habit" among the female employés of rubber-factories is said to be increasing. The inhalation of naphtha fumes produces a peculiarly agreeable inebriation. Naphtha is used to clean rubber, and is kept in large boilers, to the valve of which the female employés obtain access, and breathe the fumes. The habit was introduced from Germany, and is reported to be chiefly found in the New England States.

— The trustees of the Vermont State Insane Asylum for the insane have decided to build only the south wing of the new building at the present time. The wing will be 384 feet long with an extreme depth of 152 feet and will contain 33 beds in several dormitories and 42 single rooms, making accommodations for 75 patients. It is hoped that the foundation can be completed this fall. For the construction of the south wing there is available $85,000 the remaining $15,000 of the appropriation having been expended on the purchase of land. Completed, the building will probably cost not far from $250,000, with the central administration building, which will be 192 by 64 feet in size, and the north wing. It is calculated that the entire structure will accommodate 400 patients.

NEW YORK.

— Dr. Walter De Forest Day, who has ably filled the position of Sanitary Superintendent of the Health Department since 1873, has been compelled to resign on account of ill health, and Dr. W. A. Ewing has been appointed to the place. Dr. Ewing is well qualified to succeed Dr. Day, having had many years' experience in the department. From 1870 to 1873 he served on the vaccinnating corps and then was appointed assistant sanitary inspector. In 1876 he was promoted to be full sanitary inspector and he served in this capacity for ten years, when he resigned.

Miscellany.

DELIRIUM IN JAUNDICE.

In the *Illustrated Medical News*, May, 1889, page 149, Mr. Mallam records the case of a married woman aged forty-eight years, who was attacked with pain in abdomen on February 26, 1887. For two days she was kept under morphia, then bromide of potassium and chloral were given. There was much pain over the liver, which was increased in size, and there was pain over the right scapula: slight jaundice came on and the tongue became dry and red. A few days later the jaundice became more marked and she complained of severe headache: delirium also set in. There was no bile in the fæces, and the urine was the color of mahogany. The symptoms grew worse and it was evident that there was obstruction of the common gall-duct. On March 28th, Mr. Reeves was called in, but he did not think it a good case for operating, but on April 5th he was going to make an incision to explore the abdomen, when some bile was noticed in the stools and the operation was postponed. No more bile, however, was passed after this, and there was no improvement in the patient's condition. The delirium still persisted, but on the evening of April 15th she said she felt something go in her head, and her mind very soon became clear, after being more or less delirious for six weeks. On April 23d bile reappeared in the motions, and the patient made a quick recovery. This case is interesting in many ways: First, the

long period of delirium caused great anxiety; and, secondly, it shows the value of placing some faith in waiting for nature to assert herself, instead of trusting to the risk of an operation. — *London Medical Recorder.*

TENTH INTERNATIONAL MEDICAL CONGRESS AT BERLIN, 1890.

BUREAU: BERLIN NW., Karlstrasse 19.
July 8, 1889.

We, the undersigned, do hereby give notice, that, according to the resolution passed at the Washington meeting September 9, 1887, the Tenth International Medical Congress will be held in Berlin.

The Congress will be opened on the 4th and closed on the 9th day of August, 1890.

Detailed information as to the order of the proceedings will be issued after the meeting of the delegates of the German Medical Faculties and Medical Societies at Heidelberg on the 17th of September in the current year.

Meanwhile, we should feel sincerely obliged if you would kindly make this communication known among your medical circles, and add in the same time our cordial invitation to the Congress.

VON BERGMANN,
VIRCHOW,
WALDEYER.

PREVALENCE OF VENEREAL DISEASES IN THE BRITISH ARMY DURING 1888.

ON the motion of Mr. Cavendish Bentinck, M.P., says the *Lancet*, a return was prepared showing (1) the ratio of admissions into hospital and of constantly sick in hospital per 1,000 of strength of troops serving in the United Kingdom during the year 1888; (2) the ratio of admissions into hospital for primary venereal sores and gonorrhœa per 1,000 of strength of the troops at certain large stations in the United Kingdom (formerly under the provisions of the Contagious Diseases Acts) during the year 1888. From this it appears that the ratio per 1,000 of primary syphilis was 93.2, that of secondary syphilis 40.2, and of gonorrhœa 91.1 respectively, making a total ratio of 224.6 per 1,000 of admissions for venereal disease during the year. The ratios of men constantly sick from these diseases were — primary syphilis 8.20, secondary syphilis, 3.92, and gonorrhœa, 6.06 respectively, or a total of 18.19 per 1,000.

Turning to the second part of the return, we find that the ratio of primary sores and gonorrhœa in the districts formerly under the Contagious Diseases Acts varied considerably. The total ratio was 99 per 1,000 of primary venereal sores; 85 per 1,000 of gonorrhœa. The highest ratios are those of Portsmouth, where that of primary sores was 170, and of gonorrhœa 132 per 1,000. The next highest were those of Devonport and Plymouth; primary sores 134, gonorrhœa 109. At Windsor the ratios were 104 and 90. At Shorncliffe and Colchester the ratio of primary sores was the same, 97; the ratio of gonorrhœa was in the former place 56, in the latter 107. At Winchester, primary sores were in the ratio of 39, and gonorrhœa 73; at Canterbury, 87 and 79; in Cork, 68 and 98; at the Curragh, 55 and 57. At Maidstone there were no primary sores; gonorrhœa was at the ratio of 46 per 1,000.

It has been often said that statistics can be made to prove anything, but this cannot be said of such returns as these, which are simply a summary of facts which cannot be gainsaid. It is a serious reflection, remarks our contemporary, that out of every 1000 admissions into hospital last year, 225, or more than one-fourth were for venereal diseases. It is still more serious to realize the fact that since the Acts were repealed the ratios have much increased, being in fact, double and treble those of former years when the Acts were in force, and diseased prostitutes were sent to hospital till they were cured, instead of being permitted, as they now are, to spread these diseases broadcast.

MORPHINE-VASELINE AS A LOCAL APPLICATION IN CANCER.

MORPHINE combined with vaseline forms one of the best possible sedative applications in cases of external malignant disease, in which there is ulcerative breach of surface with continuous pain, says the writer of *The Asclepiad*. The mode of prescribing the preparation runs as follows: —

Vaseline, pure	ʒij
Chloroform	ʒij
Morphine gr.	iv.

Mix thoroughly, and make into an ointment.

By using the chloroform a larger quantity of morphine can be introduced than if the alkaloid were used alone, the distribution through the mass being more complete. The chloroform, in the proportions named, causes, as a rule, no irritation, but acts rather as a sedative. Chloroform also is a powerful antiseptic, and as such is a good remedy in the class of case under consideration.

Morphine-vaseline is most conveniently applied thinly spread over a piece of fine lint or soft linen. It is easily removable without injury to the surface upon which it is applied, and it may, therefore, be used even on surfaces from which the danger of hæmorrhage is foreseen. The dressing may be renewed twice in the course of twenty-four hours.

DRAINAGE IN GANGRENE OF THE LUNG.

THE *London Medical Recorder*, July 20th, quotes from the *Rivista Clinica*, of May, preceding, the report for a case by Malagola, in which a gangrenous lung was incised and drained successfully. A patient was admitted with intermittent fever, symptoms of gangrene of the lung supervening. As the patient was getting worse and no treatment was of any avail, intrapulmonary injections of various antiseptics were tried. The patient's state, however, became daily worse, and Dr. Montalti determined to introduce a drainage-tube into the lung. Dr. Malagola made the incision in the intercostal space immediately under the right nipple. The drainage-tube, two millimètres in diameter, was introduced for five centimèters, and every three hours it was washed out with a five per cent. solution of carbolic acid. As this caused violent cough and vomiting, sublimate solution (½ per 1000) was substituted. This was well borne and caused but little cough. The improvement was immediate, all the

severe respiratory and circulatory phenomena diminished rapidly, and the general health of the patient rapidly gained. The drainage-tube after the fourth day showed a tendency to be expelled; it was gradually shortened and taken out finally on the nineteenth day. The patient was admitted on June 29th, and left the hospital quite well on September 15th. There was distinct falling in of the chest-wall on the operated side between the clavicle and nipple.

THE VENOM OF SNAKES.

THE venom of the rattlesnake has been frequently made the subject of study, and, while its action as a poison has been generally conceded, some writers have endeavored to prove its efficacy as a drug. Surg. L. A. Waddell, M.B., as we learn from the *Lancet*, has recently been availing himself of his opportunities as a deputy sanitary commissioner in Bengal to determine a point around which it would seem that much uncertainty existed, — the curious question of the effect of serpent venom on the serpents themselves. In a paper he has published he quotes the contradictory conclusions arrived at by previous experimenters, and endeavors to show that, from the accounts of the experiments, it by no means followed that death, when it occurred, was the result of auto-toxic action. Accordingly, he felt that the question was still open, and proceeded to some very interesting investigations, conducted under different conditions of temperature and season, verifying his results by control experiments upon other animals and by post-mortem examination of the snakes he employed. In every case the fresh venom was injected into the cobra with an ordinary hypodermic syringe; the serpents operated upon were all healthy, and had recently been caught; the snakes were kept under observation from nine to fifteen days subsequently, and were then killed. The experiments generally confirm and extend the principle formulated by Fontana in 1765, that the venom is neither a poison to the snake itself nor to those of its own species. This immunity is not to be explained upon the mere fact of the animal being cold-blooded, or upon the anatomical conformation of ophidians, since most, if not all, of the non-venomous snakes are susceptible to venom. Surgeon Waddell suggests that it may result from a toleration established through frequent imbibition of the venom in the modified or attenuated form which it assumes when mixed with salivary and gastric juices and absorbed through the alimentary canal, and in support of this hypothesis he mentions the popular belief that certain snake-charmers, by a process of inoculation with venom, gain protection against the bite of a particular species of venomous snake. If this hypothesis can be verified by further experiments, it will go far towards affording indications for combating the action of the venom on man.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 27, 1889.

Deaths reported 3031; under five years of age 1601; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 1049, consumption 249, acute lung diseases 146, diarrhœal diseases 802, diphtheria and croup 86, typhoid fever 58, whooping-cough 29, malarial fever 23, measles 21, scarlet fever 15, cerebro-spinal meningitis 11, erysipelas 4. From whooping-cough New York 12, Boston 5, Philadelphia 4, Baltimore, Washington and Lynn 2 each, Chicago 1. From malarial fever, New Orleans 12, New York 4, Philadelphia 3, Baltimore and Charleston 2 each. From measles, New York 6, Chicago and Washington 6, each, Boston and New Orleans 2 each, Cambridge 1. From scarlet fever, New York 6, Philadelphia and Chicago 3 each, Baltimore, Cincinnati and Lawrence 1 each. From cerebro-spinal meningitis, New York and Chicago, 3 each, Cincinnati 2, Washington, Worcester and Springfield, 1 each. From erysipelas, Chicago 3, New York 1.

In the 28 greater towns of England and Wales with an estimated population of 9,555,406, for the week ending July 20th, the death-rate was 21.0. Deaths reported 3844: infants under one year of age 1514; acute diseases of the respiratory organs (London) 141, diarrhœa 708, measles 102, whooping-cough 86, scarlet fever 58, diphtheria 36, fever 28.

The death-rates ranged from 12.0 in Brighton to 38 1 in Portsmouth; Birmingham 24.3; Bradford 19.3; Halifax 16.7; Hull 18.6; Leeds 28.5; Leicester 26.0; Liverpool 29.2; London 18.7; Manchester 29.9; Nottingham 18.2; Sheffield 20.4; Sunderland 26.8.

In Edinburgh 15.8; Glasgow 21.9; Dublin 22.8.

The meteorological record for the week ending July 27, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending Saturday, July 27, 1889.	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.		Velocity of Wind.		State of Weather.[1]		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 27, 1889, TO AUGUST 2, 1889.

S. O. 174, Headquarters of the Army, Adjutant General's Office, Washington, July 30, 1889. By direction of the Secretary of War, so much of Par. 1, S. O. 154, July 12, 1889, A. G. O., as directs Captain LOUIS BRECHEMIN, assistant surgeon, to return to his station at the close of the encampment of the Illinois National Guard, is amended to direct him to report in person, not later than August 20, 1889, at Fort Robinson, Nebraska, for duty at that place.

Leave of absence for ten days is granted Captain WILLIAM R. HALL, assistant surgeon. Par. 5, S. O. 80, Headquarters Department of Dakota, July 27, 1889.

The leave of absence for two weeks granted Captain SAMUEL Q. ROBINSON, assistant surgeon, U. S. A., by Par. 11, S. O. 165, from these Headquarters, is hereby extended ten days. Par. 8, S. O. 172, Headquarters Division of the Atlantic, July 30, 1889.

The extension of leave of absence granted First Lieutenant ROBERT R. BALL, assistant surgeon, in S. O. 167, July 22, 1889, from this office, is further extended ten days. Par. 23, S. O. 169, A. G. O., Washington, July 24, 1889.

By Par. 9, S. O. 176, A. G. O., August 1, 1889, the leave of absence granted in S. O. 140, A. G. O., June 18, to First Lieutenant H. S. T. Harris, is further extended two months.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 3, 1889.

P. H. BRYANT, assistant surgeon, ordered to temporary duty on Iron Clads, Richmond, Va.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING AUGUST 3, 1889.

HUTTON, W. H. H., surgeon. When relieved at Mobile, Ala., to assume command of the Service at Baltimore, Md. July 23, 1889.

PURVIANCE, GEORGE, surgeon. When relieved at Baltimore, Md., to assume command of the Service at Philadelphia, Pa. July 24, 1889.

GASSAWAY, J. M., surgeon. Ordered to New Orleans, La., for temporary duty. August 2, 1889.

GOLDSBOROUGH, C. B., surgeon. Granted leave of absence for thirty days. July 29, 1889.

VAUGHAN, G. T., assistant surgeon. Ordered to Norfolk, Va., revoked; to proceed to Cairo, Ill., for temporary duty. August 1, 1889.

GROENEVELT, J. F., assistant surgeon. Relieved from duty at Gulf Quarantine Station; ordered to Mobile, Ala., for temporary duty. August 3, 1889.

SOCIETY NOTICE.

FRENCH CONGRESS OF SURGERY. — The Fourth Session of the French Congress of Surgery will be held from the 14th to the 20th of October next, at Paris, in the main amphitheatre of the *Ecole de Médecine*, under the presidency of M. le Baron Larrey. Opening Session, Monday, October 14th, at two o'clock.

The following questions are submitted to the consideration of the Congress:

(1) Results, immediate and remote, of operations practised for local tuberculosis.

(2) Surgical treatment of peritonitis.

(3) Treatment of aneurism of the extremities.

DR. S. POZZI, *Secretary-General*,
10 Place Vendome.

DEATH.

Henry S. Otis, M.D., of Hartford, Conn., died August 4, 1889.

BOOKS AND PAMPHLETS RECEIVED.

Plaies et Ligature de la Veine Fémorale. Par M. Maubrac, Aide-major. Paris, 1889.

Circulation Veineuse de la Racine de la Cuisse. Par le Dr. Maubrac, Médecin Aide-major. Bordeaux, 1888.

Original Articles.

ON SURGICAL TREATMENT OF GANGRENOUS HERNIA, WITH REPORT OF FOUR CASES.[1]

BY MAURICE H. RICHARDSON, M.D.,
Surgeon to the Massachusetts General Hospital; Assistant Professor of Anatomy in the Harvard Medical School.

DURING the past few years a great deal has been said upon this subject. Hitherto, gangrene of the intestine following prolonged strangulation has been treated by leaving the process to nature, by forming an artificial anus, or by immediate resection and return of the sutured gut to the abdominal cavity. All these methods have been advocated and followed during the past ten years. The object of surgical interference in these cases is, first, to relieve obstruction by providing an outlet for the intestinal contents; and second, to restore the continuity of the bowel. The chief question to be considered, is whether we shall do the palliative operation, and make an artificial anus, or whether we shall immediately excise the gangrenous portion of the bowel. The literature of the last three years contains many valuable contributions to this subject. McCosh[2] publishes a successful case of immediate resection and gives an excellent *résumé* of the subject, with a carefully prepared table which includes all the cases published up to the present time. In this paper the opinions of prominent surgeons are quoted for and against primary excision, that of the writer being rather in favor of its immediate performance.

Klaussner, in an elaborate article, concludes:[3] "In all cases of strangulated gangrenous hernia one should form an artificial anus, if the patient is run down, so that a long operation (one to one and a half hours) would be borne with difficulty. It is also the preferable operation for the practising physician, who is often compelled to operate under the most unfavorable circumstances or even wholly without assistance. Therefore, primary resection seems suited only to those who have a certain power of resistance against a longer operation and narcotization, as in the case of gangrene quickly following acute strangulation. So that, to put the matter in a few words, the formation of an artificial anus is slower but surer as regards recovery; unfortunately, however, it soon puts a patient into a most miserable condition; while primary resection, on the other hand, an ideal operation, is a more risky performance, but in cases of success gives perfect health in a few weeks."

Graefe, Reichel, Bergmann, all favor the formation of an artificial anus, with a view to secondary resection. Rydgier, Bansu, Roggenban, Riedel, and Kocher favor primary resection.

In regard to the operation of excision of gangrenous intestine, Klaussner says that the most important thing is to make the incisions in healthy gut; so that it is better to remove a couple of centimetres of healthy gut than to run the risk of subsequent sloughing.

Haenel[4] reports five cases of gangrenous hernia in which an artificial anus was formed. Three of these died before any attempt was made to get rid of the artificial anus — one from collapse, one from inanition, and the third from general peritonitis. In attempting to get rid of the artificial anus in the other two, and in two cases sent in from outside, success followed the three cases in which Dupuytren's method was followed, but death from fæcal peritonitis occurred in the fourth case, in which resection was performed. Haenel speaks very decidedly in favor of the formation of an artificial anus in gangrenous hernia, and all the more willingly gives preference to this procedure, rather than resection, because in the latest literature (since Reichel's statistics) he found ten cases of death in sixteen cases of primary resection; and of the six cases that recovered, two had fæcal fistula for a while. As regards getting rid of artificial anus, Haenel mentions forty-three cases of secondary circular resection, sixteen fatal, twenty-five recoveries, and two with permanent fistulæ. Hence he favored the Dupuytren method of operating wherever it is possible to do so.

Coppons[5] says: "(1) Simple enterotomy followed by the formation of an artificial anus, ought to constitute the preferable operation in gangrenous hernia. (2) Intestinal resection, more perilous, ought to be reserved for absolutely special cases, and considered as an exceptional method."

Mazzoni preferred primary resection for gangrenous hernia. Out of twenty cases thus treated in Italy, twelve were successful.

Wright, G. A.,[6] says: "Perhaps the wisest course would be to merely open the bowel at the time, and should the obstruction continue and the symptoms persist, to adopt the plan of resection a day or two later, in the meantime taking measures to render the parts as aseptic as possible."

Since the appearance of McCosh's tables, Dawborn[7] publishes a successful case of immediate resection of the intestine for gangrene. He performed immediate resection for three reasons: (1) Patient in excellent condition; (2) part of gut involved undoubtedly part of the jejunum, and hence nutrition with an artificial anus would not be well maintained; (3) the patient's bowel above the strangulation could not contain much fæces, as a thorough movement had occurred a little more than a day previously. Consequently, great pressure from retained gut contents would not be brought to bear against any intestinal sutures. 12⅞ inches removed. Czerny and Lembert sutures. Whole operation two and three-quarter hours. Actual suturing of gut, nearly one and a half hours. Thinks that Abbe's catgut rings (an improvement on Senn's plates) will shorten the time very much.

Gerster[8] had four cases of gangrenous hernia; all died. He says: "All the patients upon whom necrosed gut was found died either of collapse, shortly after completion of the operation, or of peritonitis due to infection extending from the place of strangulation. On one of them resection of the necrosed part of the gut was practised, with subsequent suture. The patient died of peritonitis. Immediate resection of the gut has little to commend it. The dangers of the infection of the peritoneum are almost insurmountable, the comprehensive preparations required for enterorrhaphy are usually not made, and, the work being extemporized, generally

lacks exactitude. In addition to this, the general condition of the patient is commonly so bad, that undue prolongation of anæsthesia would be very dangerous. Therefore, in these cases, the establishment of an artificial anus is the only thing to do."

Charles K. Briddon[9] reports a case of strangulated femoral hernia with gangrene of the intestine. He performed the operation of resection and suture. Operation lasted one and a half hours. Patient failed gradually and died the next day. The post-mortem showed no signs of peritonitis, and there was quite firm union of intestine at the point of suturing.

Walter Pye[10] referred to a case of gangrenous intestine in which he had established an artificial anus. During exertion the open bowel slipped into the abdomen and caused the death of the patient from peritonitis.

Stewart (quoted in *Lancet*) says that in twenty herniotomies he has seen, gangrenous gut had been found in two instances, and in both the bowel was opened and left *in situ*, both patients dying early from septicæmia. It was this adverse experience which led him to prefer excision of the intestine when the next case presented itself to him, which was done with success.

Fleming, J. C.[11] Male, aged forty-eight. Inguinal herniotomy performed; bowel gangrenous; laid open and slightly stitched to the external wound. Did well after the operation. A month later noted that he was distinctly emaciating and in low spirits, and also suffering extremely from the irritation of the fæces continually pouring out of the artificial anus, this irritation even preventing him from sleeping. Operation. An incision was made through the skin round the projecting end of the bowel, and about a quarter of an inch from it, and was prolonged upward. By putting the bowel on the stretch by means of ligature already applied, it was easily dissected free, and a portion pulled down with the mesentery. By following this the lower end of the bowel was found; triangle of mesentery removed three inches each way. Freshly cut edges of the gut brought together. Lembert sutures. Good recovery.

Bank, W. M.[12] Six cases of gangrenous gut; laid gut open, but did not interfere with stricture or anything else; three died and three recovered. Is strongly of the opinion that the stricture should be left alone.

Weill.[13] Artificial anus formed; 70 cm. intestine excised. Eleven weeks later operations for artificial anus; recovery. 12 and 15 cm. excised from ends of intestine; nearly one metre excised in all. Umbilical. In his own experience had, from 1873–79, fifteen cases of gangrenous hernia; thirteen died and two were left with fæcal fistulæ: a mortality of eighty-seven per cent.

In 1884, Reichel[14] collected all the published cases of circular resection of the intestine; fifty-six for gangrenous hernia; twenty-four recoveries, twenty-nine deaths; three fæcal fistulæ: a mortality of fifty-two per cent.

In a personal communication, Dr. E. H. Bradford, of Boston, Surgeon to the Boston City and Children's Hospital, expressed himself as favoring resection in gangrenous hernia, where the condition of the patient is good enough to justify the additional risk. With his permission I have availed myself of the following cases:

The first case was that of an old woman with a strangulated hernia of ten days' standing. She was in bad condition. The gangrenous gut was excised and the bowel sewed partly with the Lembert and partly with a continuous stitch. She died of shock the next day. No autopsy was allowed.

The second case was also hernia with gangrene. Excision and suture was performed. The patient died at the end of a week, because too much of the intestinal wall was turned in, leaving a lumen not larger than a pencil. Dr. Bradford feels confident that she would have got well if this had not been done.

A third case of gangrenous hernia was treated by the formation of artificial anus. The patient recovered well from the operation, but died later from inanition. The part opened proved to be the jejunum.

My experience in gangrenous hernia is derived from the following cases:

CASE I. A young woman with right femoral hernia of a week's standing. There was a large swelling in the upper part of the right thigh, extending downward and inward. Constitutional symptoms severe. A large incision was made down into the sac, which contained fæcal matter and pieces of gangrenous bowel that had become almost entirely disorganized. The ring was divided sufficiently to allow fæcal matter to escape, so that an artificial anus was established. She died of shock in twenty-four hours.

In this case it is quite evident that nothing could have been done beyond opening freely the bowel and trusting to the formation of an artificial anus. The condition of the patient was so poor that nothing beyond the most speedy operation could be thought of.

CASE II. Susan H. T., age sixty-five, married. Entered Massachusetts General Hospital, September 13, 1886. Five years ago operated upon for radical cure of hernia by injection. Had complete relief until yesterday, when she was taken with violent vomiting and pain. The old hernia was enlarged, and very tense, about the size of a goose-egg. Operation by Dr. Richardson. Incision through skin and sac of hernia, disclosing a loop of intestine very dark in color. The ring was divided and the hernia reduced. Pillars of ring sewed together and wound closed; drainage from the bottom.

September 14th. Very uncomfortable; vomiting.

September 16th. Still vomiting. Abdomen much distended. Enema. Small dejection and much wind. No relief of distention.

September 17th. Delirious; becoming weaker. Second operation.

Original incision extended and peritoneum opened. The loop of intestine in hernial sac found constricted, although above the ring. It was dark and gangrenous, and gas could be squeezed from it through numerous small perforations. The constricting band was cut and the coil of intestine withdrawn. The perforated and gangrenous portion of intestine and the mesentery connected with it was carefully excised, the incision being made well within the healthy gut. The two free ends of intestine were sewed with fine silk, by the interrupted Lembert method. The mesentery was sewed with a continuous suture. She died at 11.45 P. M. that evening, September 17th. Wound opened and,

specimen removed. The gut was already well glued up. Death from shock. No general peritonitis.

Case III. Dr. Broderick, of Charlestown, in whose practice this case occurred, has sent the following history: Catherine Corcoran, aged forty-two. Has had several children. Noticed a swelling in umbilical region a number of years ago, which gradually increased in size. At times she would have severe pain in that region which the attending physician called wind colic. I saw her for the first time on the night of October 19, 1888. She had been in bed two days, with pain in umbilical region, vomiting, thirst, and constipation. Temperature 98.6°; pulse 80. At the umbilicus was a hard tumor, the size of fist, slightly tender on pressure, and dull on percussion, and very red in color. I saw her again October 20th, at night. Temperature 99°; pulse 84; constant vomiting, and no movement from bowels for four days. Swelling at umbilicus more tender, somewhat softer and dusky red in color. I saw her a third time, October 21st, morning. Continual vomiting; pain at umbilicus severe and constant; bowels not moved. Umbilical swelling has a softer feeling and a sense of fluctuation. Temperature 99°; pulse 86. I saw her again Monday, October 22d, morning. Temperature 99.8°; pulse 88. Constant vomiting if anything enters the stomach. Bowels have not discharged anything for six days. Constant pain in umbilicus; fluctuation in swelling. When I first saw the patient my diagnosis was probable strangulated hernia, and I advised her to enter the hospital, but she refused. Treatment, morphine subcutaneously. Ice to suck. Milk and water to drink. Poultice to tumor. The first day ordered enema, but no fæcal discharge, and on third visit ordered another, with same result. I did not desire to try taxis.

Hospital Records.— "Catharine Corcoran, age forty-two. Monday, October 22, 1888. General health fairly good. For six years has had a rupture at naval, and has been troubled with it for the past four months more than usual. Bunch at umbilicus from time to time grows larger and painful, and she vomits. By lying down and taking hot drinks she recovers. After this present attack, no relief followed her usual treatment. Friday morning, October 19th, she was seized with a severe pain in umbilical region and began to vomit. Vomiting continued incessantly up to time of admission to hospital, the following Monday — three days. No sleep; no passage of flatus or fæces; abdomen very painful, tender and distended; tumor as large as two fists at umbilicus; skin over it tense, red, and in places darkly discolored, hot and œdematous; expression anxious; respiration rapid and shallow; pulse, small, thick and thready, almost imperceptible; temperature 100.5°."

Operation, 5 P. M., by electric light; under ether. Incision five inches in length, made over tumor in the median line. On opening sac small intestine found to be gangrenous. Color dark green; odor putrid and fæcal; surface shreddy. The whole sac and its contents were first thoroughly irrigated with warm solution of corrosive sublimate, 1: 5000. The ring was so tight that it was impossible to get anything through it, and the occlusion was complete. The opening was freely incised and healthy bowel drawn out. Up to this time the woman's condition had constantly improved under the anæsthetic. I believed it to be quite as easy to resect this gut and sew the ends as to make an artificial anus, and the danger of infecting the peritoneal cavity equal in both operations. I decided to perform enterorrhaphy. The living bowel was divided with scissors well beyond the line of demarcation, and the healthy ends held by the fingers of an assistant. The healthy mesenteric border was ligated with silk and left. The joint was made by a single row of Lembert sutures, and twenty-minutes were taken to apply them. Fine silk was used, threaded in round needles. The mesenteric border remained as a small puckered bunch under the line of suture. The whole joint was very satisfactory.

During the operation the parts were repeatedly irrigated with corrosive solution, and great care was taken to keep the contents of the sac out of the abdominal cavity. The bowel was then replaced, and the ring sewed up with interrupted silk sutures. Sac drained. The condition of the patient was good during the entire operation. The vomiting ceased immediately and never returned. There was a large dejection on the third day; marked diminution of distension; temperature normal. The sac discharged freely for some time. For the first few days it was distinctly fæcal in odor. Her temperature never reached 101°, except the evening after the operation, when it was 101.8° Discharged well, December 17th. In perfect health ever since.

Case IV. Dr. Colony, of Fitchburg, sends the following history of this case:

"I was first called to see the patient, Mrs. Jos. A, H., on March 11th. She is a strong, muscular woman, weighing more than two hundred pounds, and accustomed to do the hardest kind of work, and with the exception of the disease to be described, always in robust health. For the past fifteen or twenty years, an umbilical hernia has been developing, which has at last attained an enormous size, of irregular shape, and at times nearly twelve inches in diameter, heretofore partially reducible. Previously to the present attack, the patient had from time to time suffered from what she described as severe colic pains, but usually passing off without medical assistance. Had been sick several days when, Monday, March 11, 1889, upon my first visit, she was suffering from severe abdominal pains, radiating from the lower portion of the sac, which was tender, red and inflamed. Nausea and vomiting occurred, and there was obstruction of the bowels. Pulse 90; temperature 100°. On Tuesday and Wednesday the local inflammatory symptoms increased, involving an area of nearly five inches in diameter. The general symptoms were not much changed. There was a rise in temperature, 102°, and pulse 95. On Thursday, 14th, the integuments covering a large portion of the sac had become dark colored and presented a gangrenous appearance. On Friday there was an escape of fluid and sloughing. A very offensive discharge occurred, which increased for several days. On Tuesday, March 19th, in consultation with Drs. Thompson and Spring, an investigation was made without ether, and the two ends of the bowel, of what portion we were not sure, were easily located in the sloughing mass. At this date the whole sac presented a dark appearance, and no line of demarcation could be made out.

"Toward the end of the second week the local inflammatory symptoms began to improve, and a not very thick slough of the integuments began to take place. This favorable change has continued to the present time, until the integumentary portion of the

sac has gradually closed up around the ends of the bowel. A small portion of the bowel has sloughed off. The ends of the bowel each discharged partially digested fæcal matter. The general health of the patient has improved since the end of the second week, until at the present time she is able to take all the nourishment she requires, and as much as her attendants. She is also able to be about her room."

I saw this case on Friday, May 2d, with Dr. Colony. The patient looked in very robust health, and was evidently in first-class condition. There was a large irreducible umbilical hernia, covered with thin skin, through which the peristaltic movements of the small intestines could easily be seen. At the lower border of the hernia there were two conical projecting masses at the apex of which crater-like openings discharged gas and fæcal matter. Though small and constricted these openings gave free exit to the intestinal contents. The skin of the abdomen was intensely inflamed. The lower margin of the tumor ended in a deep sulcus, lined with granulations which was very difficult to keep clean. It was hard to say just what part of the small intestine had sloughed, but it was quite evident that it was removed from the stomach, not only from the character of the fæcal matter discharged but also from the rapid improvement in nutrition and general condition. The constant attendance of two sisters was necessary, and she was unable, of course, to be of any service in the care of her house, husband, and seven boys. Her life at present is not worth living.

I report this case not only because it shows the terrible condition to be expected in favorable cases of artificial anus, but it adds one more case to the list of recoveries following the establishment of artificial anus, by nature or otherwise. She has now to run the risk of a secondary operation.

(To be continued.)

THE CHEMISTRY OF ARSENIC.[1]

BY WILLIAM B. HILLS, M.D.,
Assistant Professor of Chemistry in Harvard Medical School.

ARSENIC, although one of the rarer elements, is in small quantities very widely distributed. It is found native but more commonly in combination with certain metals, notably iron, cobalt and nickel, and with sulphur. The most important arsenical ores are arsenical iron, Fe As_2; arsenical pyrites or mispickel, Fe_2 As_2 S_2; realgar, As_2 S_2; orpiment, As_2 S_3; arsenical nickel, Ni_2 As_2, and tin-white cobalt, which is composed essentially of arsenic and cobalt. Less frequently arsenious oxide and salts of arsenic acid are met with. The most abundant of these ores is mispickel, and it is from this chiefly that arsenic and its compounds are prepared on the large scale as a principal product. Large quantities are, however, obtained as a secondary product in the working of the ores of tin, copper, cobalt and nickel. The ores of arsenic are found in various parts of the world, but are especially abundant in certain European localities, as Styria, Silesia, the Hartz mountains, and in Cornwall and Devonshire in England.

Arsenic in small quantities occurs in many minerals other than those above mentioned. It is found, for example, in most specimens of iron pyrites; consequently it is a common impurity in sulphuric acid and in numerous chemical and pharmaceutical products in the preparation of which this acid is employed. The ores of bismuth frequently contain arsenic; as a result, the pharmaceutical preparations of bismuth are likely to be arsenical, unless the metal from which they are prepared is first purified, or exceptional care taken to eliminate arsenic in their preparation. The ores of zinc are usually arsenical; consequently metallic zinc, which is employed in the most important test for arsenic may contain more or less arsenic as an impurity.

The wide distribution of arsenic is of great importance in its relations to medico-legal investigations involving a question of arsenical poisoning.

(1) Since certain reagents employed in analytical work are liable to contamination with arsenic, it is the duty of the chemist, who is called upon to make an examination of the organs of the body, or of other material in a case of suspected arsenical poisoning, to ascertain that all the reagents and apparatus used in his investigations are entirely free from arsenic. For this purpose, a blank experiment, using the same reagents in essentially the same amounts, and the same apparatus, must be carried on side by side with the examination of the organs or substances under investigation. Among the reagents employed in an analysis for arsenic, sulphuric and hydrochloric acids and metallic zinc are especially liable to contain arsenic as an impurity; while sodium carbonate and potassium chlorate have occasionally been found arsenical. Glass and the glaze of porcelain may also contain arsenic, which may be communicated to certain reagents, especially the fixed alkaline hydrates. While there is no difficulty at the present time in obtaining reagents free from arsenic, yet the chemist should personally test the purity of these; and a failure to do so is properly sufficient ground for the rejection of the chemical evidence.

(2) Owing to the occasional presence of arsenic in pharmaceutical preparations, it is important, in medico-legal investigations involving the question of arsenical poisoning, that such medicines as have been administered just prior to and during the sickness of the individual supposed to have been poisoned, be submitted to the chemist for analysis, that he may be able to say, if possible, that the arsenic found in the organs or excreta could not have had its origin in such medicines. This procedure is especially necessary in cases in which subnitrate of bismuth has been administered. This preparation formerly contained, as a rule, more or less arsenic; sometimes a considerable quantity. Consequently the arsenical impurity in bismuth is invariably urged by the defence, provided bismuth has been administered, in explanation of the arsenic found. As now prepared it rarely contains more than the faintest trace of arsenic. Yet a failure to submit for analysis any sample actually administered might aid in defeating the ends of justice. Solution of ferric chloride may also be mentioned as a medicinal preparation in which an appreciable amount of arsenic may be found.

(3) On account of the wide distribution of arsenic in small quantities, traces of arsenic are occasionally found in the body in cases in which death has not been the result of poisoning. Such traces may have their origin in drugs administered during life (either arsenical preparations as Fowler's Solution, or medicines containing arsenic as an impurity), or more frequently

[1] Read before the Massachusetts Medico-Legal Society, October 3, 1888.

perhaps in the dust given off from arsenical papers or fabrics. The possibility of the latter origin of arsenic found in the organs is usually urged by the defence, even in cases in which the amount of arsenic recovered from the organs is large. In the majority of cases the quantity of arsenic found, if any, is sufficiently large to justify the opinion that it could not have had its origin in the manner suggested: and a similar opinion is warranted in case arsenic or any of its compounds is found in the stomach or intestines in the solid state. But the detection of mere traces of absorbed arsenic is by no means necessarily indicative of arsenical poison. In the case of Madame Laffarge, Orfila obtained from the body a quantity of arsenic estimated to be about the one hundred and thirtieth part of a grain. The woman was convicted. No importance whatever would be attached at the present day to the detection of this amount of arsenic in the body.

COMPOUNDS OF MEDICO-LEGAL IMPORTANCE.

In addition to metallic arsenic, the following compounds of arsenic possess more or less medico-legal importance: Arsenious oxide, called also arsenious anhydride, arsenious acid, white arsenic and arsenic: the arsenites of sodium and potassium; the aceto-arsenite of copper (Paris green, Schweinfurth green); the arseniates of sodium and potassium; arseniuretted hydrogen; the yellow sulphide of arsenic or orpiment, and the red sulphide or realgar.[2]

Metallic Arsenic.—The metallic arsenic occurring in commerce is either native arsenic or more commonly the artificial product obtained by heating arsenical iron or arsenical pyrites in a closed vessel. It is also prepared by subliming a mixture of arsenious oxide and charcoal, and may be obtained from the sulphides by heating these with a mixture of charcoal and an alkaline carbonate or potassium cyanide. It is a very brittle crystalline substance, of a steel-grey color, specific gravity about 5.75. It has a bright metallic lustre, and conducts electricity readily. Hence, although in all its chemical relations a non-metallic element, it is usually called *metallic* arsenic, to distinguish it from *white* arsenic to which the term "arsenic" is popularly applied. It undergoes no marked change in dry air at the ordinary temperature, but in moist air, especially if in the finely divided state, it absorbs oxygen with considerable rapidity and is converted to arsenious oxide; and it is probable that it is poisonous only in so far as it becomes oxidized either by exposure to the air or by contact with the fluids of the stomach and intestines. One of the substances known as fly-paper is such a mixture of arsenic and arsenious oxide, containing, it is said, from four to eleven per cent. of the latter substance. Metallic arsenic is readily volatilized, and the vapor in contact with air emits a peculiar garlic-like odor. Heated in air it takes fire and burns with a livid blue flame and evolution of dense white vapors of arsenious oxide. Its combustion is attended with the peculiar odor referred to. If pure it is insoluble in water; but when the oxidized product is boiled with water, arsenious oxide is dissolved, and may be detected by appropriate tests applied to the solution. The best solvent is concentrated nitric acid, which oxidizes it to arsenic acid. Metallic arsenic is used chiefly for the purpose of hardening lead in the manufacture of shot.

Analysis.[3] Heated in a narrow reduction tube metallic arsenic is converted to a vapor, which recondenses as a sublimate in the upper and cool part of the tube. The lower part of this sublimate presents an iron-grey appearance, and the upper part a dark-brown color, gradually fading to a grey ring in which octahedral crystals of arsenious oxide may usually be detected. Very thin sublimates have a light-brown color. An arsenical sublimate is distinguished from sublimates produced by other volatile metals as follows: (1) It is soluble in sodium hypochlorite (Labarraque's Solution). (2) If the lower part of the tube is cut off, and the sublimate heated while the tube is held in an inclined position, the arsenic is volatilized, and oxidized to arsenious oxide, which condenses in the form of octahedral crystals in the upper and cool part of the tube. This oxidation of arsenic is attended with the characteristic garlicky odor.

If arsenic is dissolved, by the aid of heat, in strong nitric acid, and the solution evaporated to dryness, a white residue of arsenic acid is obtained. This is soluble in water, and the solution thus obtained responds to the tests for arsenic acid; or the solution may be saturated with sulphur dioxide, the excess of this gas removed by heat, and the solution then tested for arsenious acid.

Arsenious Oxide.—This is called also arsenious anhydride, arsenious acid, and popularly white arsenic, flour of arsenic, arsenic and ratsbane. It is the substance usually meant when arsenic is spoken of. Medico-legally the most important of the compounds of arsenic. It is occasionally found native, and is formed artificially whenever metallic arsenic is volatilized in contact with the air. The ore from which it is obtained as the principal product is usually arsenical pyrites. It is also obtained as a bye-product in the roasting of arsenical ores of copper, tin, cobalt and nickel. The ores are roasted in furnaces, and the vapors of white arsenic conducted into large chambers in which they are condensed. The crude product is refined by subsequent resublimations. It is manufactured chiefly in the mining districts of Germany, and in Cornwall and Devonshire in England.

Arsenious oxide is a white solid, occurring in two crystalline forms and in the amorphous state. The amorphous, known also as vitreous or glassy arsenic, is formed when the vapor condenses on a surface whose temperature is but little below the volatilizing point of the oxide, so that before solidifying it passes through the semi-fluid state. It is colorless and transparent when first prepared, but gradually changes into an opaque porcelain-like mass. This change has been attributed to the passage from the amorphous to the crystalline state.

The *octahedral* variety is produced by sublimation when the vapor is cooled rapidly, so that it solidifies at once without passing through the semi-fluid state; also when hot saturated solutions are allowed to cool.

Right rhombic prisms, isomorphous with native oxide of antimony, are occasionally obtained by sublimation; also when a boiling saturated solution of the

[2] Poisoning, resulting from the domestic use of arsenic, for example from paper-hangings, glazed paper, fabrics, etc., has been recently treated in a thorough manner by Edward S. Wood, M.D., in the Report of the Massachusetts State Board of Health, Lunacy and Charity. The consideration of this subject is therefore omitted in this paper.

[3] Only such tests are described in this paper as may readily be applied by the physician to solids suspected to be arsenic or one of its compounds. Works on toxicology may be consulted for a description of wet tests for arsenic, and for information regarding the systematic examination of organic liquids or solids for arsenic.

oxide in potassium hydrate is allowed to cool (Pasteur).

As met with in commerce, powdered arsenic examined microscopically is sometimes found to consist wholly of amorphous fragments of varying size, being prepared by grinding the large masses. At other times it consists chiefly of octahedral crystals varying in size from $\frac{1}{250}$ to $\frac{1}{5000}$ of an inch in diameter, usually containing at the same time more or less fine dust and fragments produced by the breaking up of the crystals in the grinding process to which the crystalline arsenic is subjected before it is put on the market. Hence the microscopical character of the powder *may* enable one to say with tolerable certainty that a certain sample was not derived from a certain source. The factors which we may avail ourselves of in such a comparison of samples, are the crystalline or non-crystalline character of the powder, the prevailing size of the crystals or fragments, the proportion of crystals to amorphous matter, to some extent perhaps the lustre and markings of the crystals, and the presence or absence of foreign matters (the presence of charcoal, for instance, suggesting "Rough on Rats"). Microscopical examination does not, however, enable one to say that a given sample was derived from a given source; though we may say that one sample resembles another, and *may* have been originally a part of it. It should be borne in mind in comparing different samples that the characters of the substance may be materially modified by immersion in a liquid, as the contents of the stomach and articles of food and drink (smaller fragments dissolved, crystals rounded off, etc.).

White arsenic is practically destitute of taste, though at times a sweet, rough, astringent or metallic taste has been described. Its specific gravity is about 3.7, that of the vitreous variety apparently a little higher than that of the octahedral. It volatilizes at about 200° C. The vapor is colorless and odorless and condenses again on a cool surface in the form of octahedral crystals. The solubility of white arsenic in water varies with the conditions. It is, other things being equal, more soluble in hot water than in cold. The solubility, according to Wormley, depends chiefly upon the following circumstances: (1) The physical state of the oxide; (2) the relative proportions of the oxide and water present; (3) the time they have been in contact; (4) the temperature of the mixture; (5) if the mixture has been boiled, the length of time the boiling was continued; (6) the time that has elapsed since the mixture was heated. Wormley's experiments show that one part of the oxide may be dissolved in from 6.72 to 810 parts of water. The vitreous is usually considered to be more soluble than the crystalline variety; but Wormley finds that while under one set of conditions this may be true, under another the reverse may be true. Most experiments show that the solubility is more or less diminished by the presence of organic matter; but probably all liquids which are used as foods or beverages, such as milk, tea, coffee, wines and other alcoholic liquors, may hold in solution, in the quantity in which they would ordinarily be taken into the stomach, a poisonous dose of arsenic. Very large quantities may be held in suspension in thick or mucilaginous liquids, and thus taken into the system unperceived.

White arsenic, although quite heavy, has the peculiar property of floating on water in part, whether the arsenic is added to the water or the reverse. The floating particles frequently unite to form spheres enclosing a bubble of air and persistently refuse to mix with the water. Frequently the portion which sinks presents the same spherical appearance which may persist for a long time, and which is so characteristic as to attract attention. Arsenic will thus float on water for months even if the liquid is occasionally agitated.

White arsenic is more soluble in water acidulated with hydrochloric acid than in water alone. It is very soluble in the fixed alkaline hydrates, less soluble in ammonium hydrate. By nitric acid it is dissolved and oxidized to arsenic acid. White arsenic is used largely for the preparation of other compounds of arsenic, as a mordant, as an antiseptic, to some extent in medicine, for the extermination of vermin, and for other minor purposes. Among vermin exterminators, "Rough on Rats" is a mixture of white arsenic and charcoal; the "Buffalo Carpet Bug Annihilator" contains white arsenic as its poisonous ingredient. Some fly-waters are solutions of this substance or alkaline arsenites in water sweetened with sugar.

Analysis.—The recognition of solid arsenious oxide presents no difficulties. Its crystalline form (octahedra or modifications of octahedra) is very characteristic. Heated on charcoal in the reducing blowpipe flame it is volatilized in the form of white vapors, with the emission of a garlic-like odor. In this experiment, the oxide is first reduced by the carbon to metallic arsenic, which is in turn reoxidized in the air to arsenious oxide. Heated in a reduction tube it volatilizes without fusing, and recondenses in the cool part of the tube in the form of octahedral crystals, or crystals which are modifications of octahedra. Other white powders furnish crystalline sublimates, but most of these melt before volatilizing, and none of them condense in octahedral crystals. The reduction test for arsenic is one of the most valuable tests and is thus performed. Place a bit of arsenious oxide in the closed end of a narrow reduction tube, and a little distance above this place a piece of recently ignited charcoal. First heat the charcoal to redness, and then the oxide, keeping the charcoal at the same time hot. The oxide is volatilized and in passing over the hot charcoal loses its oxygen and is deposited in the cool part of the tube above as a sublimate of metallic arsenic, the characters of which have been described. This reduction may also be effected by a dry mixture of sodium carbonate and potassium cyanide, or by potassium ferrocyanide which has been previously dried at 100° C.

Pure aqueous solutions of arsenious oxide have a feebly acid reaction. If a drop of such a solution is allowed to evaporate spontaneously on a glass slide, the oxide is left in the form of octahedral crystals. The residue thus obtained by evaporation may be tested as above described. The most important tests for arsenious acid in solution are the following: (1) the ammonio-silver nitrate test; (2) the ammonio-copper sulphate test; (3) the sulphuretted hydrogen test; (4) Reinsch's test; (5) Marsh's test. Most of these tests require a skill in manipulation possessed only by the trained chemist, and all of them are subject to certain fallacies which can be avoided only by a thorough knowledge of the chemical properties not only of the compounds of arsenic, but of those of certain other elements. A satisfactory description of them cannot therefore be given in this paper. Of the tests

mentioned, Marsh's test is the most important as well as the most delicate; while Reinsch's test is the only one applicable in the presence of organic matter. In the performance of the latter test it is important to remember that both metallic copper and hydrochloric acid frequently contain traces of arsenic. The purity of these reagents should therefore be first determined.

Arsenites. — These are compounds of arsenious acid with metals. The alkaline arsenites are at times sources of poisoning. Potassium arsenite which is used in medicine under the name of "Fowler's Solution" is the most important of these. Both potassium and sodium arsenites are used considerably in solution and in the form of a soap by taxidermists. They are white, non-volatile, very soluble compounds, and respond to all the reactions for arsenious acid, with the exception of the sublimation test, and to those for the constituent metals. Fowler's Solution is further characterized by its odor and color.

Aceto-arsenite of copper (Paris green or Schweinfurth green), is used largely as a pigment, and for the purpose of killing the potato-bug. Owing to the ease with which it can be obtained, it has given rise to numerous cases of accidental and suicidal poisoning. It is characterized by a vivid-green color when pure, a paler green when adulterated, as is frequently the case, with chalk or gypsum. Heated in a closed tube it furnishes a sublimate composed of octahedral crystals of arsenious oxide, while a black residue (cupric oxide) remains behind. It is insoluble in water, but wholly soluble, if pure, in ammonium hydrate with formation of a deep blue solution. If this solution is allowed to stand till the excess of ammonia has escaped, and a drop or two of a solution of silver nitrate is then added, a yellow precipitate of silver arsenite is obtained. On systematic analysis it affords the reactions for copper and arsenic.

(To be continued.)

REPORT ON FOODS, DRUGS AND THEIR ADULTERATIONS.

BY BENNETT F. DAVENPORT, M.D.

SOJA.

M. LECERF[1] calls attention to the nutritive value of soja hispida seeds as exceeding lean beef. As a flour it is rich in albuminoids, while containing only about three and one-quarter per cent. of starchy and sugary matter. It could well, therefore, be used in bread for diabetics. This has been found to remain fresh for five days. M. Petit has shown that the seeds contain a purgative which should be removed before grinding. According to M. R. Blondel, it does not at all contain any true starch.

COAL-TAR COLORS IN FOODS.

Dr. Weyl[2] has made important investigations as to the relation between chemical constitution and physiological actions, which are of great interest in relation to the use of coal-tar colors in food. Of the "nitroso" colors he finds "naphthol-green, B" to be harmless to dogs in fifteen to thirty grain doses daily for a fortnight. Of the "nitro" colors he finds "dinitrocresol or artificial saffron" to be likewise harmless; while Martin's yellow, which is well tolerated by rabbits, will, in small doses, kill medium-sized dogs. A sulpho acid, however, of the Martin's yellow, known as "naphthol yellow, S," is harmless in four times as large doses. The "nitro" compound, picric acid, has long been known to be poisonous. Of amantias there are two commercial brands. That from the Berlin aniline factory appears not to be poisonous to rabbits, while that from Basle has proved very injurious to men. Dr. Weyl has not yet found any of the "azo" coloring compounds to be poisonous, while three "saffranin" preparations were all so.

Cazeneuve[3] reports that he finds the following coal-tar colors not injurious to health: roccellin or soluble red, the sodium salt of the sulphonic acid of rosaniline; a purple-red diazo-compound (Bordeaux red, B); Ponceau, R; orange, I; yellow, N. S.; ordinary induline; Coupier's blue; acid green; and a soluble yellow sodium salt, the full technical name for which, as well as for the other ten colors mentioned, necessary for their perfect identification, must be sought in the original article. He finds the sodium salts of sulphonic acids are not poisonous, as a rule; while the nitro compounds are. Methylene blue he finds is injurious.

BENZOIC ACID AS A FOOD PRESERVATIVE.

The consultative committee of public hygiene in France, have reported, through M. Pouchet,[4] that benzoic acid should not be allowed to be used as a preservative in foods. The reason was that, as an antiseptic, it would interfere with normal digestion. The use of any antiseptic or antifermentative is irrational, from the point of view of nutrition.

COCOANUT AS A VERMIFUGE.[5]

The cocoanut has been used as a vermifuge for centuries in India, being considered equally efficient for expelling the flat worm as male-fern oil, kouso, pomegranate root or turpentine; being, moreover, as pleasant to the taste as they are offensive.

KERATINIZED PILLS.

The residue left after testing such tissues as horn or feather quills successively with ether, alcohol, water, and diluted acids, is known as keratin. This substance, which is insoluble in the gastric juice, is dissolved by the alkaline bile in the small intestines. It has therefore been recommended by Unna and Beierdorf[6] as a coating for pills, which it is desirable for any reason should not act until they have passed the stomach, an object sometimes of great importance.

THIOCAMP.

a compound of sulphur dioxide with camphor, is commended by Dr. J. E. Reynolds, of Dublin, as a disinfectant, it being a convenient form of liquified sulphurous-acid gas obtainable without the use of pressure. The fluid can be stored at ordinary temperature in bottles without pressure; yet, when exposed in a thin layer to the air, it gradually liberates 308 times its own volume of the acid gas. This compound has long been known as a chemical, having been described years ago by H. Schulze.[7]

MORPHINE VASELINE.

Dr. Richardson,[8] in a late number of his journal, recommends a mixture of four grains morphine to the

[7] Pharm. Zeitung, 1889, p. 416.
[8] Asclepiad, p. 147.

ounce of vaseline as a sedative application in cases of external malignant disease in which there is ulceration with continuous pain. A little chloroform aids the mechanical mixing; it is best applied spread on lint.

MILK SUGAR AS A DIURETIC.

M. G. Sée [9] lately called the attention of the French Academy of Medicine to the powerful diuretic action of milk sugar. He attributes to this the like action of whole milk or its whey.

CAPSICUM COLOR.

Dr. Sauerman [10] has reported to the Physiological Society of Berlin, that a non-pungent coloring matter, obtainable from capsicum, when fed to young canary birds before they had moulted, had a marked effect in heightening the color of their feathers.

FRAUDULENT MERCURIAL OINTMENT AND LAUDANUM.

The Pennsylvania Pharmaceutical Association committee [11] on adulterations, have reported finding some blue ointment composed merely of lard, colored with Prussian blue. Of 77 samples of laudanum collected from all parts of the State, as well as New York City and Baltimore, but four were of full officinal strength; nine more were near enough to fall within the limits of reasonable error; while five failed to yield any weighable amount of morphine. The remaining fifty-nine samples were all classed as bad. Nearly all of the poor samples were either the bottled preparation from country stores or from manufacturers who supply that trade.

Forty-two samples of laudanum collected by the State Drug-Examiner of New Jersey,[12] were found upon analysis in thirty-four cases, to fall below the legal standard.

COMPOSITION AND IDENTIFICATION OF THE NATURAL DISTILLED SPIRITS.

M. X. Rocques,[13] of the *Laboratoire Municipale de Paris*, has reported a scheme for the identification of the natural distilled spirits, among which he includes the brandies from grapes, apples, pears, and other small fruits; also rum and whiskey. He distills nine successive fractions of one-tenth each, using Lebel and Henninger column, and subjects them each to the action of a series of five reagents. In these reactions he claims a notable difference between the natural and artificial product is shown in all cases, and in his report gives the details of his results.

COVERING THE SENSE OF TASTE FOR BITTER AND SWEET,

B. Berthold [14] reports that directly after chewing the leaves of gymnema sylvestre, a strong woody shrub from an asclepiadea found in Assam, on the Coromandel coast, and in Africa, the sense of taste for bitters and sweets is lost for one to two hours, but only for these two effects. Sugar then tastes like sand, and quinine pills like chalk. The leaves themselves, taste at first bitter and then slightly acid. The Hindoos have long used the bark as an antidote against snake-bite.

BORIC ACID A NORMAL CONSTITUENT OF WINE.

Dr. Baumert,[15] of Halle, reports that he finds boric acid to be always present in natural wines grown in any of the wine producing countries of Europe, as well as in those of California.

TEA ADULTERATIONS FOR THE AMERICAN MARKET.

Consul Crowell,[16] of Amoy, reports that a large portion of the Amoy oolong tea is poorly cultivated, picked and dried; that it is dirty and adulterated, and was called "stuff," in the last year's report of the Amoy Commissioner of Customs, who added that it "was alone wanted in America." This last, the consul says, is true; for nearly the entire crop of Amoy oolongs — bad and unfit often for use as they are — are annually marketed in the United States, and, he thinks, the American public ought to be warned and protected against this so-called tea.

INGLUVIN.

Dr. A. Gawalowski [17] reports that he finds ingluvin originating from a New York firm to consist simply of three parts table salt with 97 parts of a crude pepsin containing starch.

HEAVY CALCINED MAGNESIA.

An American house [18] has reported that an English brand of heavy calcined magnesia, sold in competition with theirs, has, upon analysis, been found to consist simply of hydrated gypsum.

FUMIGATING PASTILS FOR FLIES AND MOSQUITOES.

Vomacka [19] commends a mixture of 100 parts each of coarsely powdered thyme leaves, lavender flowers and Dalmatian insect powder, with 90 of saltpetre, 9 of potash chlorate, 20 of gum tragacanth, and sufficient water to make into a mass. This forms an efficient and pleasant pastil for killing such insects.

WHALE EXTRACT.

A new food preparation has been introduced into Europe under the name of whale extract. This, from its cheapness is likely to become more widely known. It has, by the analysis of Dr. Otto Schweissinger,[20] of Dresden, the following composition here shown in connection with an average commercial meat extract:

	Whale.	Meat.
Water	23.23 %	23.01 %
Organic Matter, including Nitrogenous	59.07	60.00
Nitrogenous	4.12	7.44
Mineral Matter, including Salt	17.70	17.18
Phosphoric Acid	5.30	

ALUM BAKING-POWDERS.

Prof. J. W. Mallett, of the University of Virginia, has come to the following conclusions from his experiments with 27 samples of 17 brands of alum baking-powders: (1) These powders, as found in retail trade, give off very different proportions of carbolic acid gas, and therefore require to be used in different proportions with the same quantity of flour, some of the inferior powders in largely increased amount, to produce the requisite porosity in bread. (2) In these powders there is generally present an excess of the alkaline ingredient, but this excess varies in amount; and there is sometimes found, on the contrary, an ex-

[15] Berichte Deutsch. Chem. Gesell, 1888, p. 3290.
[16] United States Consular Report, April, 1889, p. 589.
[17] Pharm. Zeitung, xxxiii, p. 522.
[18] Amer. Pharm. Jour., 1889, p. 121.
[19] Druggists' Circular, 1889, p. 20.
[20] Pharm. Centralb., xxx, p. 96.

cess of acid material. (3) On moistening with water, these powders, even when containing an excess of alkaline material, yield small quantities of aluminum and calcium in a soluble condition. (4) As a consequence of the common employment of calcium acid phosphate along with alum in the manufacture of baking-powders, these, after use in bread, leave at any rate most of their aluminium in the form of phosphate. When alum alone is used, the phosphate is replaced by hydroxide. (5) The temperature to which the interior of bread is exposed in baking does not exceed 212° F. (6) At the temperature of 212° F., neither the water of combination of aluminum hydroxide, nor the whole of the associated water of either this or the phosphate, is removed in baking bread containing these substances as residues from baking-powder. (7) In doses not very greatly exceeding such quantities as may be derived from bread as commonly used, aluminum hydroxide and phosphate produce, or produced in experiments upon myself, an inhibitory effect upon gastric digestion. (8) This effect is probably a consequence of the fact that a part of the aluminum unites with the acid of the gastric juice, and is taken up into solution, while at the same time the remainder of the aluminum hydroxide or phosphate throws down in insoluble form the organic substances constituting the peptic ferment. (9) Partial precipitation in insoluble form of some of the organic matter of food may probably also be brought about by the presence of the aluminum compounds in question. (10) From the general nature of the results obtained, the conclusion may fairly be deduced, that, not only alum itself, but the residues which its use in baking-powder leaves in bread, cannot be viewed as harmless, but must be ranked as objectionable, and should be avoided when the object aimed at is the production of wholesome bread.

Clinical Department.

A CASE OF PARTIAL PLACENTA PRÆVIA IN A MULTIPARA.[1]

Recurrent Hæmorrhage between the Seventh and Eighth Month. Delivery by Manual Dilatation.

BY A. D. SINCLAIR, M.D.

Mrs. ——, about forty-two years of age, a multipara, had painless hæmorrhage about seven months and a half after pregnancy. The bleeding recurred again and again for two weeks but whether profuse or not I did not ascertain. She then called her family physician who tamponed the vagina during five consecutive days. He found the cervix very rigid and the os uteri small until the fifth day, when the cervix softened. At this time I was called on to aid in the case. The patient showed the loss of blood and was nervous. The vagina was largely dilated by the sponge tampons, and the cervix could be easily dilated, manually. Forced delivery was advised. The womb was readily entered and the child turned and extracted by the feet in about fifteen minutes. The placenta was found freed from the uterine wall on the left side to the extent of about two inches, but its upper segment was unnaturally adherent to the uterine wall. The placenta was smaller, thinner and more feeble than ordinary, contraction and retraction normal. The uterine cavity was thoroughly cleansed with warm water containing 1 to 3000 corrosive sublimate, the patient cared for in every way and made comfortable. Three days later she was reported to have had a decided chill with rise of temperature and pulse. She was given a uterine douche by her physician, and two grains of quinine in pill every hour, with the result that the temperature and pulse both fell and in a day or two were normal, and did not rise again. She made a good recovery. The infant, a feeble thing, lived three or four days.

[1] Read before the Obstetrical Society of Boston, April 13, 1889.

A CASE OF PUERPERAL ECLAMPSIA.[1]

BY T. J BRODERICK, M.D.

Mrs. M. W., thirty years of age, primipara, has enjoyed health up to her present illness. Married, June 27, 1888; and menstruated, July 6, 1888, for the last time. Her father is alive, her mother died twenty-seven years ago from some difficulty during child-birth. Mrs. W. went along in pregnancy comfortably, to within two weeks of her delivery, at which time her present illness began. During this time she noticed her eyelids and feet swollen; headache troubled her; nausea, vomiting, and loss of appetite.

On Sunday, March 24th, she ate her supper, and retired at 10 P. M. She did not sleep, and at 12 P. M. pains were present in her abdomen, which she ascribed to the food she had eaten. At 1 o'clock Monday morning she suddenly became unconscious, foamed at the mouth, eyelids opened, eyes stared, limbs stiffened. She became conscious in about half an hour, but did not feel well.

The pains in the abdomen continuing, with occasional nausea and vomiting and headache, I was sent for, and saw her for the first time, Monday the 25th, at 4.30 A. M. She was in bed, and complained of pains in her abdomen, headache, nausea and vomiting. Her eyelids and feet were œdematous, the right foot more so than left. Pulse 84. Uterus enlarged to about eight months' pregnancy, with contractions causing the pains in abdomen. Fœtal heart-sounds heard on the right side of abdomen, and one hundred and thirty-eight beats to the minute. I requested her to move to the opposite side of the bed to make a vaginal examination. She raised herself on her elbow, but suddenly fell back unconscious, on the bed. Her eyelids closed, then opened, eyes fixed, limbs stiffened, respiration ceased, soon followed by twitching of muscles of the face, moving the arms and legs, stertorous respiration and slight frothy saliva at mouth, and gradual return of consciousness in an hour. Then followed a second convulsion, severer than the first. I saw, during the tonic period marked cyanosis and swelling of face, absence of respiration, slow and irregular pulse, followed by the chronic stage with loud, stertorous and irregular respiration, rapid and feeble pulse, frothy saliva at mouth, and convulsive twitching of muscles of face and extremities. From this time she remained unconscious. A third convulsion followed in one hour, and a fourth in two hours after, or at 9 A. M., having had five convulsions in nine hours.

[1] Read by invitation before the Obstetrical Society of Boston, April 13, 1889.

At this time Dr. Forster was asked to see her in consultation. She was in bed, unconscious, breathing normally, skin perspiring freely, lips red and face swollen, pulse 84–92, and temperature 99° half an hour before. No urine or fæces passed. Delivery by internal version was decided as the proper course to pursue, but as the patient was comfortable at the time, delay was counselled for a time. At 11.30 A. M., a sixth convulsion occurred, not so severe as the previous three, and at 1.45 P. M., a seventh followed; after which I drew off urine (in amount about two ounces), with blood, and about one-half per cent. of albumen present. Then, at consultation, it was deemed advisable to empty uterus as soon as possible. From 2.30 P. M. to 4 P. M. she had two slight convulsions. At 4.45 P. M. or seventeen hours after the first convulsion, version was begun, Dr. Forster, Dearborn and Broderick present. During dilatation of vagina a slight convulsion occurred, and the hand entered the vagina in twenty minutes. During dilatation of os the membranes were accidentally ruptured. Before complete dilatation of os pulsation could be felt in chord but it was slow and irregular. When the hand entered the uterine cavity in one and three-quarters hours no pulsation was present. The position of child was verified as O. R. A. The left leg was seized, the child turned and head expelled in two hours from the commencement of dilatation of vagina. The placenta was expelled in ten minutes with slight hæmorrhage. The pulse varied from 120 to 135 per minute during version. Fifteen minutes after delivery the pulse dropped to 108 per minute. Within the next two hours, two slight convulsions occurred. At 10 P. M., or three hours after delivery, a severe hæmorrhage occurred. Pulse 135, and for a time absent from wrist; lips and face pale; limbs cool; tossing arms and body about the bed, and sighing. The hæmorrhage ceased and in one hour the pulse was 120, and patient quiet in bed.

At 6 A. M., Tuesday 26th, pulse 92, temperature 98.5°; no urine passed since 2 P. M. the previous day. At 10 A. M. I drew off her urine; specific gravity 1014, slightly acid, albumen about one-third per cent. She remained semi-conscious during the day. At 6 P. M., Tuesday, temperature 99°, pulse 94. Comfortable Tuesday night and conscious Wednesday morning with temperature 99.5°, pulse 100. Urinated voluntarily, passing nine ounces; specific gravity 1014, pale in color, albumen present. Œdema of eyelids and feet disappearing, and on the seventh day entirely absent. The highest temperature 101° was on the evening of the fourth and morning of the fifth day. The highest pulse after hæmorrhages was at the same time, 115–112. On the 14th day temperature and pulse normal, and have continued so to the present time. The last twenty-four hours the urine in amount is thirty-five ounces, color pale, specific gravity 1016, reaction slightly acid, albumen about one-sixth to one-eighth per cent.

Diagnosis.— Puerperal eclampsia, caused by uræmic poisoning from acute Bright's disease.

Prognosis.— Mother alive, child dead.

Treatment.— When first seen and diagnosis made, I gave her a quarter of a grain of morphine subcutaneously, and followed it with a warm, moist air-bath and within half an hour her body and limbs were perspiring freely. Three-fourths of an hour after the morphine I administered ether, and kept her under the influence of it with occasional intermission, till after delivery; two and one-half hours after commencing anæsthesia I gave her twenty-five grains of chloral by rectum, and in one hour repeated it. After expulsion of child, a subcutaneous injection of ergot, and expulsion of placenta by pressure on uterus. When post-partum hæmorrhage occurred, she received thirty minims of fluid extract of ergot subcutaneously and thirty minims of ether and firm pressure on the uterus and warmth to extremities. The after-treatment was rest in bed, milk diet and water freely.

A CASE OF PUERPERAL ECLAMPSIA AT THE SIXTH MONTH, TERMINATING FATALLY.[1]

BY DAVID A. COLLINS, M.D.

MRS. C., primipara, aged twenty-four, in January last noticed a slight swelling about the feet and ankles which gradually extended up both legs, involving eventually the abdomen, arms, hands and face, there being a slight puffiness of the lower eyelids. As this state of affairs occasioned no unpleasant symptoms, it was allowed to pass unheeded until about the first of March, when she began to complain of severe headaches, nausea and vomiting, for which on the 11th of March she consulted her family physician, Dr. E. N. Whittier, who examined her urine and found it to contain about three-quarters per cent. of albumen.

The next morning, the 12th, at 5. A. M. the first convulsion occurred. I arrived at 7 A. M. and found Dr. E. J. Forster in attendance. He had placed her under ether, she having had three convulsions in the two hours. A hot-air bath was applied and Dr. Whittier was sent for. In the meantime I relieved Dr. Forster for two hours during which time she had three convulsions. At 10 A. M. Dr. Whittier arrived, and the induction of labor was begun by manual manipulations. At the end of two and one-half hours the os was dilated sufficiently to admit the hand, when the membranes were ruptured and a foot brought down. The trunk was delivered without much difficulty, but it was found that the cervix had contracted quite firmly about the neck, for which manual dilatation was again tried with but little success. The traction on the trunk caused a tearing of the neck, which continued to tear until it was necessary to completely sever the body from the head. The forceps were now applied to the head, but were ultimately abandoned through fear of lacerating the cervix; and it was decided to do craniotomy, which was performed by Dr. Forster, he perforating the head through the mouth, and delivering with the cranioclast. The placenta was expressed ten minutes after. A bi-chloride douche (1-3000) was given and antiseptic pads applied. It was now 1.30 P. M., just three and one-half hours since the induction of labor was begun. At 2 P. M. the next convulsion occurred, and the ether was again applied, and a subcutaneous injection of morphia (gr. ¼) was given. At 3 P. M. she had another convulsion, and at 3.30, the injection of morphia was repeated and the hot-air bath was given with little effect. At 4 P. M. a subcutaneous injection of brandy was given. The next convulsion occurred at 5 P. M., from which time up to 10 P. M., she had four very violent spasms. At 11 P. M. the catheter was passed and eight ounces of urine were drawn.

[1] Read, by invitation, before the Obstetrical Society of Boston, April 13, 1889.

March 13th. First convulsion at 3 A. M., followed by another at 7.30 A. M. At 8 A. M. the hot-air bath was applied, and she was given an injection of ten minims each of digitalis and brandy, which was repeated at 10.25 A. M. At 10.30, Dr. W. L. Richardson arrived, and ordered one-sixth of a grain of pilocarpine, which was given at 10.55 A. M. (I would state here that our reason for not giving pilocarpine earlier was the fear of producing profuse salivation while we were obliged to keep our patient in a state of complete anæsthesia.) This was tried, but as she reached a semi-conscious state she was seized with another convulsion. The axillary temperature at noon was 106.2°, pulse 150, respiration 20; at 3 P. M. it was 105.2°, pulse 142, and respiration 26. The catheter was passed at 5 P. M. and four ounces of urine drawn which contained about three-quarters per cent. of albumen. At 5.30, the bi-chloride douche (1-3000) was given. Lochia good. At 5.40, repeated the injection of pilocarpine. Temperature at 6 P. M. 104.2°, pulse 150, respiration 20. The next convulsion occurred at 8.30. At 9 P. M. temperature 106, pulse 160, respiration 26. At 11 P. M. the last convulsion occurred. At 12 temperature 108°, pulse 155, respiration 35.

March 14th. Catheter passed at 1 A. M. (no urine in the bladder) after which time the patient began to fail. The ether was discontinued at 3 A. M. Temperature at that hour 105.2°, pulse 150, respiration 30. At 6 A. M. the temperature was 104.2°, pulse 160, respiration 24; at 9 A. M. temperature 106, pulse 170, respiration 32. The brandy and digitalis injection was given at 10.30, and repeated at 11.15 A. M. Temperature at noon 105°, pulse 164, respiration 28. At 3 P. M. she was given another injection of brandy and digitalis, the temperature now being 107.8°, pulse 168, respiration 30. At 3.30 P. M. an injection of brandy was given. About 4 P. M. she vomited, the material having a highly urinous odor. At 6.45, another injection of brandy was given. At 9 P. M. the temperature was 107°, pulse 170, respiration 24. After this hour she began to sink quite rapidly until 10 P. M., when she died, just sixty-five hours since the commencement of the convulsions, of which she had nineteen, seven being ante-partum and twelve post-partum.

A CASE OF HYDRENCEPHALOCELE.[1]

BY HORACE E. MARION, M.D.

MALE child, sixty days. At birth, January 28th, there was a tumor, pediculated, from over site of posterior fontanelle, as large as the child's head. At birth the face presented, chin under the pubes. Labor rapid, without complications, as was the convalescence of mother. Infant was tended on a pillow placed on a thin piece of board the size of pillow, and fed from a bottle, it being so difficult for mother to hold child to breast; besides, it was not believed that the child would live, so thin was the wall of the tumor in many places. It was translucent over every part, and so heavy that the child could not move its head at all, but was obliged to lay as placed. The forehead was markedly retreating.

The head and tumor grew, but the body and limbs did not. He was shown at Massachusetts General Hospital, when three and one-half weeks old. At the age of five weeks, I aspirated, removing about two-thirds of a pint of clear fluid, as clear and limpid as water. The whole tumor collapsed, except in the upper portion, which was translucent and was supposed to be another cyst or compartment. The puncture was at the pedicle, directed into the tumor. From the aspirations I felt comparatively certain that it contained nothing but fluid and perhaps some gelatinous material. The irregular contour of the posterior fontanelle could easily be made out.

It would have been better to have tried to have evacuated the whole tumor. I did not persist, as I thought I had sufficiently demonstrated its character, and beside I wished to produce as little shock as possible. Within twenty-four hours the tumor had completely refilled.

From this time the child grew more and more of a care. The body and limbs seemed to emaciate. There was a constant mucus discharge from the nose. In one place on the tumor there was a scab from which there was more or less oozing.

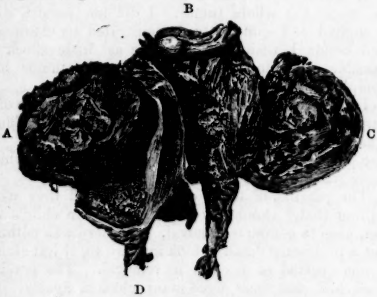
The parents, of their own accord, said they were willing that I should try anything for the child's relief, even to complete removal. As there was nothing but a protracted death to look forward to, if left alone, it was decided to attempt its removal. The parents were told that there were many chances against the child's going through an operation.

Dr. R. R. Andrews kindly and very artistically photographed the baby. Dr. M. H. Richardson kindly assisted, and gave me the advantage of his rare tact in such doubtful operations.

Making a snip with the scissors over one of the places that seemed but the merest film, it proved to be gelatinous, and a much deeper cut had to be made. The contents of the tumor were evacuated; it was made up of several separate compartments or cysts, which had to be evacuated separately. At the pedicle there was more resistance than in the gelatinous portion above. This proved to be brain substance, a small portion of which was removed in cutting off the redundant skin. The flaps were hurriedly stitched together over the brain substance, the child looking from the first as if it would be impossible to finish

[1] Read by invitation, before the Obstetrical Society, of Boston, April 13, 1889.

the operation. Indeed, I was indebted to Dr. Richardson for much timely help.



The wound was dressed with antiseptic cotton, and the child given to its mother; it died about half an hour after the operation.

No further examination of child's head was allowed.

TUBAL PREGNANCY: OPERATION, RECOVERY.[1]

BY GEORGE HAVEN, M.D.

MRS. M. consulted me on March 27, 1889, and gave the following history. Is thirty-one years old; has been married for ten years, and is the mother of five children, the youngest being now seventeen months old. She remained in bed for five days after her last confinement, and felt perfectly well and strong. Thirteen months after the birth of the child, she menstruated for the first time, the flow lasting for three weeks. She now felt much pain in lower abdomen and back, and was compelled to remain in bed from one to three days each week; had very little appetite, and vomited almost constantly. Nine weeks later she had one or two labor pains and passed a mass about the size of a pear. She now grew rapidly worse, having much more pain, and rarely leaving her bed. Says that when the pain came on, her abdomen was very tense, that her knees were flexed upon it, and that the slightest weight gave her great pain. The bowels were constipated, and when a movement was produced, the pain was excruciating; vomited constantly. Morphia was given in solution, a teaspoonful of the mixture being taken p. r. n.

A, Mass in tube. B, Broad ligament. C, Ovary. D, Uterine end of tube.

She looked pale and anxious; abdominal wall lax; examination painful; Douglas's fossa was filled by a mass of uncertain shape, which extended towards the right side; the uterus was pushed forward, felt large, but was freely movable. Laporatomy advised. She was asked to see Dr. C. M. Green, who also advised an operation.

On April 5th she went to a private hospital, and on the 6th I opened her abdomen. Dr. Green was kind enough to be present, Drs. Reynolds, Lovett and Sears assisting. The peritoneum was thickened by old inflammation. The mass was easily felt on the right side, and was adherent to the sides of the pelvis, with adhesions running in all directions. It seemed at first an almost hopeless task to free it; but after much tearing, it was brought outside of the abdomen. The larger adhesions were tied and cut; the tube, ovary, and broad ligament were all removed together. The tissues were very friable, and it was only by tying very lightly that the ligatures were prevented from cutting. The abdominal cavity was washed out with warm water, and the wound closed with seven silver sutures. A drainage-tube was inserted, but was removed on the second day.

The patient left the hospital on the twentieth day after the operation. The temperature was never over 100°, and the highest pulse was 90. I have seen her twice since she left. She looks like a different woman, and says she feels perfectly well. Dr. H. H. Sears kindly examined the specimen for me, and says, "The most interesting part of your specimen; namely, the mass in the tube, showed at place of insertion, under the microscope, the presence of chorionic villi, thereby settling the diagnosis of tubal pregnancy."

[1] Reported by invitation, to the Obstetrical Society of Boston, April 13, 1889.

Reports of Societies.

AMERICAN OPHTHALMOLOGICAL SOCIETY.[1]

AFTERNOON SESSION.

THE TREATMENT OF CARIES AND NECROSIS OF THE ORBIT,

by DR. H. KNAPP, of New York.

The upper wall of the orbit is the most frequent seat of disease and here its consequences are most dangerous. In every case of caries and necrosis of the orbit the condition of the neighboring cavities and especially the nose should be carefully investigated. Foci of suppuration should be freely opened, the cavity thoroughly cleansed and drainage established. This can be well accomplished by small silver tubes provided with flanges. Rough bone should be scraped away with a sharp spoon, necrosed portions of bone should be removed as soon as they become loose or when they can be detached without injury to adjacent tissues. The eye-ball should be protected and if there is insufficient closure of the lids, a plastic operation should not be postponed until the cornea becomes ulcerated from exposure.

MULTIPLE CYSTS OF THE IRIS OCCURRING IN BOTH EYES,

by DR. H. W. WILLIAMS, Boston.

The subject was a girl nine years of age. In the right eye there was a projection resembling a large cyst extending from the upper margin of the pupil. A similar growth projected from the temporal border. At the inner part there were two small pedunculated growths. All were of the color of the iris. In the left eye, two somewhat oval cysts filled the pupillary space. Through the square opening left in each pupil there was a little oblique vision.

SARCOMA OF THE OPTIC NERVE.

by DR. T. Y. SUTPHEN, of Newark.

The patient was ten years of age. The tumor involved the left orbit and was of two years' duration.

[1] Concluded from page 137 of the Journal.

It was of a mushroom shape and sprang from the optic nerve. It size was 6 in. by 5¼ in., and 2 in. thick. It was readily removed with curved scissors. As much as possible of the nerve was removed.

EXTENSIVE VASCULAR GROWTH IN THE VITREOUS.

by DR. GEORGE C. HARLAN, Philadelphia.

The patient a woman, fifty years of age, presented herself November 29, 1888, on account of disturbance of vision. Examination of the right eye, showed the fundus to be slightly hazy, with small dull white spots about the macula, the remains of old hæmorrhages but no recent exudation. The disc was obscured by a delicate network of vessels. Otherwise there was no opacity. There was no stroma. Up to March 2, 1889, there had been several retinal hæmorrhages, but there had been nochange in the vascular membrane. Vision had been reduced to $\frac{20}{70}$.

EXTRACTION FROM THE VITREOUS OF PIECES OF STEEL BY THE MAGNET.

by DR. O. F. WADSWORTH, Boston.

The author described two cases in which the piece of steel was removed by passing an electro-magnet into the vitreous through an opening in the sclera. In the second case, the operation was followed some weeks later by a separation of the retina beginning at a point opposite that at which the puncture was made.

CORNEAL TRANSPLANTATION.

by DR. J. O. TANSLEY, of New York.

The speaker reported a case in which he had done this operation for opacity of the cornea. At the first operation the opacity was not removed to its full depth and although the cornea cleared to a certain extent, the result was not satisfactory. The operation was therefore repeated, but without any improvement in vision. In both operations there was primary union of the graft and in neither was there any inflammatory reaction.

DISCUSSION.

DR. L. WEBSTER FOX, Philadelphia: I have performed the same operation in the case of opacity of the cornea where the patient could just distinguish light from darkness. The graft healed readily without inflammatory reaction, and the patient obtained useful vision and could almost count fingers.

AN ANALYSIS OF SOME OF THE OCULAR SYMPTOMS OBSERVED IN SO-CALLED GENERAL PARESIS.

by DR. CHARLES A. OLIVER, Philadelphia.

These observations were made on twenty well-marked cases of general paralysis of the insane. The study was limited to subjects in the so-called second stage of the disease, where the psychical symptoms had become of such a character as to necessitate control and where motor and sensory derangement had become more or less manifest. Care was taken that each subject was seemingly free from any extraneous general disease or local disorder, and the entire study was limited to the male sex so as to escape any conflicting and complicating changes that might appear in connection with the many diseases peculiar to the female sex. Thirty observations were made resulting in the following summary:

(1) The sensory changes herein described, which have been limited to unequal optic nerve degeneration, decrease of retinal circulation, with subnormal direct and eccentric vision for both form and color, distinctly show lowered sensory response.

(2) The motor symptoms, consisting in unequal and feeble movement of the irides, causing inequality and irregularity of pupillary areas, the peculiar form of ataxic nystagmus, the slight loss of ciliary tone, all express want of proper muscle action, — true paresis.

(3) The peculiarly local conditions shown in the fundus, such as the pigment massings, the crescents of absorption, the disturbed and granular condition of the choroid, etc., all indicate wear and tear of an abused and irritated organ.

(4) Therefore, these observations upon the ocular apparatus, which were most probably made during the second stage of the disease known as general paralysis of the insane, show not only local changes, but distinctly demonstrate that the series of sensory motor disturbances found, are but the peripheral expressions of one of the many indices of gradual loss of neural strength and power in this disease.

DR. GEORGE C. HARLAN, of Philadelphia, reported a case of

HYSTERICAL BLINDNESS

of ten years' duration in a male twenty two years of age.

DR. SAMUEL B. ST. JOHN, of Hartford, described

A CASE OF HEMIANOPSIA WITH PECULIAR CEREBRAL SYMPTOMS.

DR. B. ALEXANDER RANDALL, read a paper on

SIMPLE TESTS OF THE OCULAR MUSCLE.

DR. T. Y. SUTPHEN, of Newark, N. J., reported

A CASE OF DOUBLE PURULENT CHOROIDITIS RESULTING FROM MENINGITIS.

February 23, 1887, was called in consultation to see G. W. B., a robust farmer, aged thirty-nine years. He had always been healthy, with the exception of an occasional "bilious headache." Never had any specific trouble. The history was that on February 9th, he came in at noon perspiring very freely. That evening he suffered with intense headache. The next morning he was apparently well, but at breakfast had a violent chill with aching of the whole body, this was followed by high fever. Leaving the breakfast-table was the last that the man remembered for three months. From this time the patient rolled and tossed in bed without decided delirium, but being in a stupid condition and easily restrained. Questions were answered only after frequent repetition and the replies ran into complete incoherence. On the third day of the illness the body became quite rigid with the head thrown backwards. On the fourth day, the left hand and forearm became swollen and the right eye inflamed, the left eye became inflamed on the tenth day. Later the left foot became swollen. The swelling of the hand and foot lasted about a week and then subsided. The fever then became less violent and the general condition improved but the mental sluggishness remained. There was no paralysis, no convulsions, no vomiting. At the end of the third week he had a slight chill and another after he was out of bed.

At present the man is apparently in good health. He has lost none of his functions, and his mind is perfectly clear. When first seen by the writer the eyes were in the following condition: No swelling of the lids; moderate pericorneal injection; cornea clear; anterior cham-

ber normal in depth; irides slightly discolored; pupils moderately dilated, with a yellowish reflex from the anterior portion of the vitreous. There was no perception of light; no tenderness on pressure, but a marked lessening of the tension of the globe. Three days later, the anterior chamber in each eye was obliterated by pressure from behind the lens; the eyeballs being harder than normal. One week later, the anterior chamber was again restored and tension had again fallen much below the normal. From that time there was progressive atrophy of both eyes until now there is left only the greatly shrunken globes, with of course, absolute blindness.

In this case there must have been an extension of the intra-cranial inflammation along the sheath of the nerves and not a forcing of the products of inflammation forwards, as sufficient pressure within the cranium to produce this must evidently have become apparent by more or less paralysis.

The case is reported simply as a clinical contribution to this somewhat rare and obscure trouble which is certain to be met with in the course of practice.

THURSDAY — MORNING SESSION.

CONTRIBUTIONS TO THE SUBJECT OF TUMORS OF THE ORBIT AND NEIGHBORING CAVITIES,

by DR. C. S. BULL, New York.

CASE I was an adenoma sarcoma of the lachrymal gland. It was operated on two years ago. There has been no return.

CASE II was one of abscess of the ethmoid cells, frontal sinus and orbit in a male aged forty-six years. It was opened, washed out and drained. There was perfect healing.

CASE III was tumor of the maxillary antrum, nasal fossa, ethmoid cells, orbit and cranial cavity. The eye was enucleated and the maxillary antrum cleaned out. A large opening was found through the orbit into the anterior fossa of the skull and through this the tumor extended. The evening following the operation the patient became comatose and died the next morning.

DISCUSSION.

DR. H. KNAPP, New York: The report of these cases shows the necessity of early operation in all cases of tumors of the orbit or near the orbit.

DR. B. A. REEVE, Canada: In a number of these cases of empyema of the frontal sinus, I have found hypertrophy of the middle turbinated bone. This is a point of importance in etiology and prophylaxis.

CASE OF DOUBLE CHOKED DISC DUE TO INTRACRANIAL TUMOR, WITH AUTOPSY,

by DR. C. S. BULL, New York.

The patient, a young married woman, twenty-three years of age, was seen June 30, 1888. In February, 1888, had a miscarriage and was quite ill for a couple of weeks. There was dull headache at vertex. This became more severe. During April, there were occasional attacks of diplopia. During May there was failing vision. When examined, $V = \frac{18}{xx}$ in each eye. Accommodation was normal. There was no peripheral limitation of the field of vision either for form or color. There was an irregular negative scotoma for all colors. There was marked exudative neuro-retinitis with hemorrhages in both eyes. Urine proved normal on examination. The only symptoms of intracranial disease were the lesions of the optic nerve and the headache at the vertex. The diagnosis was intracranial tumor at the base of the brain. Vision rapidly failed, and by September 25th there was no perception of light. The mental faculties gradually became impaired. Right hemianæsthesia came on. The patient died May 5, 1889. Autopsy showed a tumor involving the corpora quadrigemina and extending to the anterior crura of the cerebellum. The growth appeared to be a glio-sarcoma.

DR. O. F. WADSWORTH, Boston, reported a case of torticollis cured by

TENOTOMY OF THE EXTERNAL RECTUS.

PARTIAL TENOTOMIES IN CASES OF NEURASTHENIA WITH INSUFFICIENCY OF THE OCULAR MUSCLES,

by DR. MYLES STANDISH, Boston.

The author reported five cases in which he had performed this operation on account of constant headache, inability to use the eyes and neurasthenic symptoms. In all but one there was marked and prompt relief of the local and general symptoms by the operation. Cases requiring operation are comparatively few.

NOTES ON SOME VAGARIES OF ACCOMMODATION,

by DR. DAVID COGGIN, Salem.

One case was of hypermetropic astigmatism passing into myopia. A case of recurrent spasm of accommodation was also reported. The third case was one of temporary anomaly of sight occurring daily. In the morning could see well, but in the afternoon could not recognize objects across the street. Double vision also occurred. The disturbance is gradually disappearing.

EFFECT UPON THE ACCOMMODATION OF A PATIENT'S EYE CAUSED BY LOOKING INTO A MIRROR SET OBLIQUELY IN THE ROOM DURING OPHTHALMOSCOPIC EXAMINATION,

by DR. E. E. HOLT, Portland.

Directing the patient to look with one eye into a mirror set obliquely while the other was examined with the ophthalmoscope an element of ease was found in making the examination and of comfort and steadiness on the part of the patient never experienced before. The eye fatigues quickly in looking at a single object. Looking into the oblique mirror gives the impression of gazing into the distance. A notable change in the pupil will be observed when the patient is directed to look at an object at the distance of the mirror and when he is directed to look at objects reflected from it.

PARALYSIS OF THE SPHINCTER IRIDIS,

by DR. O. F. WADSWORTH, Boston.

A case was reported of paralysis of the sphincter iridis, without affection of the accommodation, lasting several months and following the instillation of homatropine in both eyes.

DISCUSSION.

DR. SAMUEL THEOBALD, Baltimore: In all such cases it is important to exclude malingering. It would be possible for the patient by the use of a weak solution to keep up the mydriasis without affecting the accommodation.

DR. SAMUEL D. RISLEY, Philadelphia: Another

practical explanation of such cases is the use of a pipette previously used for a solution of a mydriatic, for a solution which contains no mydriatic.

DR. JOHN GREEN, St. Louis, presented a series of

GEOMETRICAL CONSTRUCTIONS ILLUSTRATING CERTAIN CASES OF OBLIQUE PENCILS REFRACTED AT CYLINDRICAL AND SPHERICAL SURFACES.

Dr. John Green also read a paper on

SOME OF THE STEREOSCOPIC ALTERATIONS EVOKED BY UNEQUAL GLASSES PLACED BEFORE THE TWO EYES.

DR. SAMUEL THEOBALD, Baltimore, presented a paper on

THE EMPLOYMENT OF OLEATE OF VERATRIA TO FACILITATE THE DETERMINATION OF ERRORS OF REFRACTION.

A mydriatic affords valuable aid in myopia and in hypermetropia, but in astigmatism its use is not so satisfactory. In astigmatism he had found great help from the use of a 10 per cent. oleate of veratria to the temple and forehead once a day for three or four days. This seems to exert a quieting effect upon the ciliary muscle, and especially of the radiating fibres, and lessens the tendency to asymetrical accommodation. The following rule was formulated in regard to the correction of astigmatism. When the astigmatism is according to the rule, we need correct only that which is readily made manifest. On the other hand, in astigmatism against the rule, we are warranted in correcting fully every part of the defect which can be rendered manifest.

THE INEFFICIENCY OF HYDROBROMATE OF HOMATROPINE IN CONTROLLING THE ACCOMMODATION FOR THE PURPOSE OF FITTING GLASSES,

by DR. E. E. HOLT, Portland.

The experience of the writer was that this drug could not be relied upon. He reported one case in which the latent hypermetropia revealed by three per cent. solution of hydrobromate of homatropine was just one-half of that revealed by one per cent. solution of atropia.

DISCUSSION.

DR. EDWARD JACKSON, Philadelphia: I have found homatropine entirely satisfactory when used properly. The instillations must be repeated at short intervals, five or ten minutes, and three or four instillations practised. The effect rapidly passes off, and the examination must be made within one or two hours. I have followed the use of homatropine by another mydriatic without alteration in the result.

AMETROPIA AS DETERMINED UNDER COMPLETE MYDRIASIS,

by DR. EDWARD JACKSON, Philadelphia.

He had examined 4,000 eyes under complete paralysis, and presented the following table of his results. These were compared with results obtained by another observer without mydriasis.

	With Mydriasis.	Without Mydriasis.
Compound hyperopic astigmatism	40 %	9½ %
" myopic "	9	11
Simple hyperopic "	6	16½
" myopic "	2	24
Mixed astigmatism	6½	2
Hyperopia	31	10
Myopia	4	9½
Emmetropia	1½	17½

DR. JACKSON also presented a paper on

ACCURACY IN THE PRESCRIPTION OF PRISMS.

DR. W. S. DENNETT, New York, read a paper in which he suggested a

NEW UNIT OF ANGULAR MEASUREMENT FOR PRISMATIC GLASSES.

DR. GEORGE C. HARLAN, of Philadelphia, exhibited

PERISCOPIC–CYLINDRICAL AND SPHERO–CYLINDRICAL LENSES.

DR. W. F. MITTENDORF, New York, presented

A CASE OF AMBLYOPIA DUE TO CHLORAL HYDRATE.

The object was to put on record a case of toxic amblyopia, due to chloral hydrate. The patient had for six months been in the habit of taking 40–60 grains of the drug at night to induce sleep. Suspension of the drug relieved the amblyopia.

EXECUTIVE SESSION.

Officers for ensuing year: *President*, Dr. Hasket Derby, Boston; *Vice-President*, Dr. George C. Harlan, Philadelphia; *Secretary and Treasurer*, Dr. Samuel B. St. John, Hartford; *Corresponding Secretary*, Dr. J. S. Trout, Brooklyn; *Delegate to the Executive Committee of the Congress of American Physicians and Surgeons*, Dr. John Green, St. Louis; *Alternate*, Dr. D. B. St. John Roosa, New York.

The following were elected to membership: Dr. Carl Koller, New York; R A. Reese, Toronto, Can.; Dr. David Harrower, Jr., Worcester, Mass.; and Dr. Geo. E. de Schweinitz, Philadelphia.

The Society then adjourned to meet at the Hotel Kaaterskill, the third Wednesday of July, 1890.

MEETING OF THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

APRIL 13, 1889, the President, DR. J. P. REYNOLDS, in the chair.

DR. D. A. COLLINS read, by invitation,

A CASE OF PUERPERAL ECLAMPSIA AT THE SIXTH MONTH, TERMINATING FATALLY.[1]

DR. T. J. BRODERICK read, by invitation,

A CASE OF PUERPERAL ECLAMPSIA.[2]

DR. SINCLAIR spoke of the great importance of thoroughly dilating and tiring out the muscles of the cervix. If turning is attempted before this is accomplished great difficulty is encountered in the delivery of the after-coming head, and lacerations of the cervix occur. There is a great temptation to turn as soon as the hand has entered the uterus, and before the cervix is thoroughly dilated. The longest time he had spent in dilating the cervix was four hours, the shortest five minutes. He thought the average time needed was about an hour to an hour and a quarter.

DR. RICHARDSON thought that two hours was about the average time needed for this procedure.

DR. FOSTER had found the dilatation of the cervix

[1] See page 158 of the Journal.
[2] See page 157 of the Journal.

to be more readily accomplished in cases of placenta prævia than in eclampsia.

DR. SINCLAIR said that this depended on the amount of hæmorrhage. If this had been profuse, the tissues were relaxed and the cervix was easily dilated.

DR. WHITTIER remarked that in Dr. Collins's case three men alternated in dilating the cervix.

DR. RICHARDSON placed great reliance in cases of eclampsia, on pilocarpine given energetically in doses of one-sixth to one-quarter of a grain, and repeated in half an hour if necessary. The hot-air bath was employed at the same time. He was not afraid of salivation, and had never seen any bad effects from the use of pilocarpine. As soon as profuse diaphoresis occurred the prognosis at once changes and becomes favorable, unless there is chronic disease of the kidneys; and he asked whether any one had seen any dangerous effects from pilocarpine.

Morphia, he now believed, might retard the action of the kidneys, therefore should not be used. Ether need not be used continuously; but at the first sign of a convulsion it should be given to mitigate, if not to prevent, the convulsion. Immediate delivery should, of course, be resorted to. He had noticed that post-partum hæmorrhage was common in uræmic convulsions, and this seems to be nature's way of blood-letting. Cases in which this occurs generally do better than the others. The two cases reported were cases in point.

DR. J. P. REYNOLDS had come to the conclusion, from the study of a considerable number of cases, that no good effect could be obtained from the intermittent use of ether in comparison with the continuous use of the same. As he had never seen convulsions recur when the ether was given continuously, he should always prefer this method; and he asked the question whether continuous etherization did not always prevent the recurrence of convulsions.

DR. SINCLAIR agreed that ether should, in these cases, be given continuously. Before the days of pilocarpine, calomel and jalap were depended on.

DR. C. E. STEADMAN spoke of a patient to whom pilocarpine produced such extreme salivation that he was afraid she would choke to death, the patient being under ether. No effect was produced on the skin, although a hot-air bath was given at the same time.

DR. E. REYNOLDS wished to lay stress on the importance of immediate delivery, as every fresh eclamptic seizure was an element of danger. The prophylaxis he considered also of great importance. Cases are common where there is marked œdema, headache, vomiting, concentrated urine with albumen and casts, and where convulsions seem imminent. He had had marked success in the treatment of these cases, even if they were seen for the first time only a few days before confinement. He relied for treatment on free catharsis together with the use of the tinct. ferri chloridi. He referred to a case reported by him a year ago treated successfully by Epsom salts.

DR. SINCLAIR spoke of a case he had seen in consultation, and advised immediate delivery. This was refused for twenty-four hours, during which the patient had twenty-seven convulsions. At the end of this time she was delivered artificially, and she died nine hours later.

The PRESIDENT, in summing up, assumed that the Society would admit the following facts:

(1) That there is nothing to be gained by waiting in cases of puerperal eclampsia.

(2) That the continuous administration of ether has not been known to allow the reappearance of convulsions.

(3) That slow manual dilation and emptying of the uterus is repeatedly successful.

DR. G. HAVEN, present by invitation, showed a

SPECIMEN OF TUBAL PREGNANCY

he had removed by laparotomy, and gave a report of the case.[3]

DR. GREEN, who had seen the case with Dr Haven, said that no previous diagnosis of tubal pregnancy had been made, and that the reason for the operation was the severe pain and continued vomiting, together with the presence of the tumor.

The PRESIDENT asked the Society whether a nursing woman, whose menses return at the first or second month, is more likely to become pregnant than one who does not menstruate.

DR. RICHARDSON replied that, as soon as she menstruates, she is liable to become pregnant. He was surprised to find from a German author, that, in an analysis of some one thousand cases, menstruation returns in the majority of nursing women at the third or fourth month; and his own inquiries in this direction confirmed this statement, and he thought that the majority of women conceive again while nursing.

DR. GREEN wished to confirm these observations, and added that among the lower classes there are many who have not menstruated for years, pregnancies coming at such frequent intervals.

DR. SINCLAIR reported

A CASE OF PARTIAL PLACENTA PRÆVIA IN A MULTIPARA; RECURRENT HÆMORRHAGE BETWEEN THE SEVENTH AND EIGHTH MONTH; DELIVERY BY MANUAL DILATION.[4]

DR. H. E. MARION, reported by invitation,

A CASE OF HYDRENCEPHALOCELE, AND SHOWED PHOTOGRAPHS.[5]

SEMI-ANNUAL MEETING OF THE WHITE MOUNTAIN MEDICAL SOCIETY.

L. W. HANSON, M.D., SECRETARY, *pro tem.*

THE Semi-annual Meeting of the White Mountain Medical Society was held in the old chapel of Dartmouth College, at Hanover, N. H., August 1st and 2d. The Connecticut River and White River Medical Societies both met at the same time and place, by invitation of the White Mountain Society. Upon invitation, several members of the faculty of Dartmouth Medical College, which is now in session, kindly consented to take leading parts, and speak upon subjects pertaining to their respective specialties. This was a new departure for this Society, but proved very gratifying and beneficial to all present.

The meeting was called to order at 3 o'clock, P. M., August 1st, by the President, DR. GEORGE W. MCGREGOR, of Littleton, N. H., who invited the presidents of the visiting societies, Professor Frost and

[3] See page 160 of the Journal.
[4] See page 157 of the Journal.
[5] See page 159 of the Journal.

Dr. Wood, to seats upon the platform. The Secretary, DR. C. R. GIBSON, being absent, DR. L. W. HANSON, of Bradford, Vt., was appointed Secretary, *pro tem.*

PROFESSOR CONNOR, of Cincinnati, Ohio, spoke on

THE RADICAL CURE OF HERNIA,

giving a brief history of the various operations proposed, and the present most approved plan of operating.

PROFESSOR WEBSTER, of New York, followed with remarks upon

ACUTE GLAUCOMA,

intended to assist the general practitioner in the diagnosis and preliminary treatment of this disease.

PROFESSOR HOOPER, of Boston, then gave an address on

MODERN SURGICAL METHODS OF TREATING OBSTRUCTIVE DISEASES OF THE NOSE AND NASO-PHARYNX.

At the Evening Session PROF. PAUL F. MUNDÉ, of New York, spoke on

SYMPTOMS AND TREATMENT OF FIBROIDS OF THE UTERUS,

in a very plain and practical manner.

PROFESSOR FIELD, of Newton, Mass., read an essay on

SULPHONAL,

giving his experience with the drug.

The Society then adjourned until Friday morning, August 2d, at nine o'clock, when PROFESSOR PARISH, of Philadelphia, spoke upon

ANTISEPTIC OBSTETRICS,

which elicited a lively discussion.

PROFESSOR COWLES, of Somerville, Mass., closed, speaking on the

MECHANISM OF INSANITY.

All the papers and addresses were able and of a practical character; and all present felt that the meeting had been a great success, and one that no member of the societies represented could afford to miss. The thanks of the societies are due Professors Frost and Smith, of Hanover, for their kind offices in arranging for the meeting and the pleasure of the members. A similar meeting is hoped for next year.

Recent Literature.

Diseases of Women. By DR. F. H. DAVENPORT. Octavo, 311 pages. Philadelphia: Lea Bros. & Co.

This book has two objects: in the first place, to give the student clearly, but with considerable detail, the elementary principles of the methods of examination, and the simpler forms of treatment of the most common diseases of the pelvic organs; and in the second place, to help the general practitioner to understand and treat the gynecological cases which he meets with in the course of his every-day practice. It does not consider the operative part of gynecology, neither does the author intend it to be anything more than the most elementary treatise on the subject.

It is written in a most pleasing style and the reader will find it difficult to put it aside until he has perused every page. We recognize the work of Dr. H. P. Quincy in many of the illustrations; and the clearness and accuracy of this part of the book greatly enhance its value. We do not remember to have seen elsewhere so good a description and perfect illustration of the Sims position.

We have never before seen any exact rules given for the measurement of the vagina for the adaptation of uterine supports; which are here clearly set forth, more particularly in regard to the posterior malpositions. It is our opinion that many of the more elaborate treatise on gynecology would do well to incorporate this chapter in their future editions.

Every gynecological student would do well to preface his course of study by reading this book, and every general practitioner should possess it, if alone for the chapter treating of uterine displacements, the fittings of pessaries, their introduction and care.

The classification of some of the subjects into chapters of symptoms, as amenorrhœa, dysmenorrhœa and menorrhagia, is entirely admissable in this volume. We grant this division has many advantages to the student: we should, however, take decided exceptions to it if the work were a more systematic treatise on gynecology, believing as we do that the only proper division of such subjects is that based on the pathological process which creates such symptoms.

We would suggest, in the next edition, the correction of the following misprints: On page 196 the substitution of "R," for "H" in the name of Dr. J. R. Chadwick; and on page 280, third line from the bottom, the substitution of "hæmostatic action" for "cauterization." The negative pole only has the power of cauterization." The paper, printing and general style of the book is the best, which is what we have a right to expect coming from the house of these well-known publishers.

We can heartily recommend this volume to all interested in the subject of gynecology.

— Mr. Francis H. Underwood, late United States Consul at Glasgow, has found a subject which he considered important enough to make the theme of an official report, in the diet of the poor of Glasgow. It seems that some time ago these people abandoned oatmeal, the traditional staff of life in Scotland, in favor of white bread and tea. This exchange was, according to Mr. Underwood, a most unfortunate one for their physical well-being. To it he ascribes the bodily degeneration and especially the deformities which are very common among the people of that city.

— A source of arsenical poisoning has been described in the columns of the *Lancet* by Dr. McClure, in Indian muslins. A patient of his suffered from arsenical poisoning, and all attempts to trace how the poison entered her system failed, until it was found that for nearly two years she had been working among Indian muslins, tearing them up and making them into covers for sofa-cushions, curtains, and many kinds of home draperies. The muslins were examined, and found to contain arsenic. The patient was removed from her muslins, and rapidly recovered.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 15, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

FRENCH INTERNATIONAL CONGRESS FOR THE SUPPRESSION OF ALCOHOLISM: REPORT OF THE SENATE COMMISSION.

IN the report of the above-named Congress, whose sessions were lately held in Paris (from July 29 to August 1, 1889), the old and familiar statement again appears from the official statistics of different European countries, as presented by the referee, that criminality and mental alienation follow a march parallel with the consumption of alcoholic beverages.

The question was discussed whether the number of places where liquor is sold influences the prevalence of drinking usages, and it was shown by figures, that the greater the number of dram-shops in a given locality, the larger the proportion of inhabitants that become addicted to intemperate habits. So plain did this appear, that one of the speakers (Dr. Drysdale, physician-in-chief to the Metropolitan Free Hospital, London), gave as his opinion that one of the best means for repressing the abuse of ardent spirits was to diminish the number of liquor-shops. This view was, however, combated by M. Causderlier, who declared that this measure had not been successful in Holland, where some years ago, the number of drinking-saloons was greatly reduced, and where alcoholism, insanity and criminality had remained the same as before the application of this restrictive measure. With this declaration, M. Milliet, Director of the Statistical Board of the Swiss Confederation, and M. Iscovesco, of Moldavia, agreed. Both these speakers stated that in their respective countries there had been governmental restrictions of the sale of intoxicating drinks, the number of retail shops having been reduced to a certain maximum per canton; in none of these districts had there been any sensible abatement in the evils of alcoholism. It was, however, thought by the majority of those present that the restriction of the number of dram-shops was a step in the right direction, and that high license (*augmentation de la patente*) was a measure calculated somewhat to repress drinking habits. We fail to notice that any more rigorous means of repression were proposed.

In this connection it is interesting to recall to mind the report a short time since presented to the French Senate by a commissioner appointed by that body to inquire into the consumption of alcohol in France, as much from the point of view of the public health and morality, as from that of the national exchequer. It appears from this report, that drinking usages in France have been lamentably on the increase the past fifty years, the average consumption of alcohol per head having quadrupled. Thus, in 1831, it was one litre per head; in 1884, the figure was four litres. The use of ardent spirits, moreover, has steadily gained on the wine-drinking habit, distilled liquors having largely superseded the fermented product of the grape. This is especially so in localities where, owing to the phylloxera, the vine-growing industry has failed.

The commission shows by unimpeachable figures that in those regions where distilled liquors are the habitual intoxicants, the evils of drunkenness attain their maximum, while comparatively little of such abuses is seen in districts, unfortunately too few, where the native wines constitute the popular beverage. It has further established the trite fact "that the number of crimes and offences against good morals is exactly in ratio with the consumption of alcohol in each of the seven great divisions of France." Alcoholism also "produces still other more deleterious effects, which effect the vital force of the country." "We refer," says the commission, "to the influence which the exaggerated consumption of alcohol (and we mean especially those forms known as ardent spirits or distilled liquors), has on the human constitution; it being a fact that the health of children almost always suffers from the alcoholic excesses of the parent. We may attribute, in part, the phenomenon of the continued diminution in our population, so noticeable in many parts of our territory, to the increase in the consumption of alcoholic liquors. In Normandy, for instance, the mortality of young children is frightful, and if the use of ardent spirits is not the sole cause of the lessening of the population in this country and in certain departments (Jura, Basses-Alpes, Lotet-Garonne, etc.), it certainly contributes to the increase of mortality, as well as to the physical enfeeblement of the race."

The commission next proceeds to show that the number of accidental deaths and suicides has increased in the ratio of prevalence of habits of intemperance, and that the proportion of cases of mental alienation due to alcohol has been steadily augmenting. "From 1,496, which was the total number during the quinquennial period of 1861–1865, the number of insane whose mental disease was due to alcohol in the forty-six departmental asylums, has gone on increasing, and from 1881 to 1885 had attained the figure of 7,387; in other words, the proportion of insane whose affection was due to alcoholism, in 1861 was eight per cent. of

those admitted to the asylums; it rose in 1885 to sixteen per cent!"

Similar facts are given with regard to the perpetration of crimes, but we have not space for these statistics, though of interest to every advocate of social reform.

BACTERIA IN MILK AND ITS PRODUCTS.

DURING the past year investigations on the bacteria of milk have been carried on in the laboratory of Storr's School Agricultural Experiment Station, under the direction of H. W. Conn, Professor of Biology in Wesleyan University, and we deem the subject of sufficient medical importance to call attention to some of the more interesting results, which have already been published in the bulletin of the station for July.

It has been found that milk is a medium in which bacteria grow with the greatest readiness. Some thirty or forty species were found floating in the air in the vicinity of the station. All of these were to be found in cream. Although they grew readily in milk yet cream seemed to be a better medium; probably because it kept longer without putrifying, and thus allowed some of the slower growing species time to develop. Butter is not so good, apparently from a deficiency of albuminous matter. The sweetest butter always contains some bacteria; when they become numerous, the butter becomes tainted.

Milk when first drawn from a healthy cow is free from bacteria; but the short exposure to the air in the act of milking is sufficient to contaminate it. Of eight sterilized tubes having milk drawn directly into them from a carefully washed teat by clean hands, and each tube then plugged with sterile cotton, seven became sour within a few days, and were found to contain many bacteria. The eighth remained sweet for a long time, yet it eventually also changed. Ordinarially, however, the number of bacteria in the air is of little importance compared to those from unclean vessels, which are the great source of infection. In ripened cream each drop has been found to contain from 10,000 to 100,000 bacteria (more of the larger number), and of about thirty species.

Two or three of the species usually found in milk are characteristic. Of these one, the bacillus acidi lactici, produces the ordinary souring of milk. Another, the oidium lactis, grows rapidly, yet seems to produce no important change in milk. The first is always found to be very abundant in the air in warm weather, but at times during a cold winter it is almost absent. Then milk could be exposed in a perfectly clean vessel to the open air for two weeks without going through the characteristic change of souring, yet it would finally curdle with a peculiar odor of decay.

Considered as to their mode of action, four different classes of bacteria were met with in milk. Some induced, at ordinary temperature, the change commonly known as souring. Some others would grow rapidly at such a temperature, but would produce like results only at some higher temperatures. Others would not decompose the milk sugar with the formation of acids and curds at all. but would leave the milk fluid, and sometimes decidedly alkaline, still others though making curds, would produce no acid, but make the milk alkaline instead. The larger number of the species, however, produce both acid and curds at some temperature.

The manner of curdling was found to differ greatly, in some cases a hard curd with a clear whey was formed; in others the curd has no clear whey separated from it, while in other cases the whole milk is turned into a semi-gelatinous mass. With some bacteria the curd is easily broken or cracked, while with others it is very tenacious, sticky and slimy. Sometimes the curd was dissolved in a few days, the milk becoming a clear transparent fluid. In these instances the curd seemed to undergo a change similar to digestion, that is, conversion into peptones.

A characteristic odor was also given off, which differed widely with the varying species of bacteria, smelling like sour bread, soft-soap, salt mackerel, pigs, or a barn-yard, and often of putrefaction.

In so-called ripened cream, bacteria in almost inconceivable abundance are always to be found. The more important results of the process in the cream are the souring, the decomposition of the albuminous matter present, and the development of the desirable flavor. The decomposition of the entangling fibrin liberates the fat globules, whereby their collection together by churning is greatly facilitated. A butter made from such a cream may keep the longer in that it is more free from the albuminous matter necessary for the growth of bacteria, although it would contain a greater number than a sweet-cream butter would in the beginning.

The use of sal-soda in washing, and of "live steam" in the after-drying of milk vessels are of great practical importance, in that the former can thoroughly remove both the fat and curds left from the milk, while the latter will effectually sterilize anything which may be left.

IS THERE AN ELIXIR OF LIFE?

IT is the silly season, and it is perhaps not unnatural that the daily press should have made the most of Brown-Sequard's alleged discovery (see this journal, present volume, page 49), and country and metropolitan newspapers have gravely and comically given the announcement to their readers, with more or less comment and elaboration thereon. As for the attitude of medical journals — we are certain that but for the reputation of Brown-Séquard, very few would have noticed the "discovery."

A correspondent of one of the newspapers asks, "Is an elixir of life possible?" And the editor occupies a column with a learned disquisition on the subject, in which he shows more knowledge of mediæval lore than of sound physiology. But the subject is being

taken up by charlatans and quacks, and is capable of doing mischief.

The sooner the general public, and especially septuagenarian readers of the latest sensation understand that for the physically used up and worn out there is no secret of rejuvenation, no elixir of youth, the better. There is no animal or vegetable product, from whatever animal or whatever gland, and however appropriated by the senile organism (by ingestion or injection), that can put back the march of the fell destroyer by one day — except, indeed, so far as it acts as a vital stimulant or nutrient, and how can any stimulant or nutrient undo the effects of atheroma, fatty degeneration, senile atrophy!

We hope we may soon hear the last of Brown-Sequard's disgusting advice to old men, and we cannot refrain in this connection from reiterating the well-known physiological truths: (1) That there is no proof that the secretion of the reproductive glands is the vital fluid *par excellence*, or that its loss is *per se* a cause of enfeeblement; (2) that all artificial excitation of the reproductive apparatus is debilitating, especially to the aged; (3) that the exhaustion which follows sexual orethism is due, not to the loss of a secretion, but to excitation of the nervous system.

MEDICAL NOTES.

— Dr. Henry C. Coe, has been appointed Professor of Gynecology in the New York Polyclinic, to fill the vacancy made by the death of Dr. James B. Hunter.

— The Trustees of the Cook County Hospital, Chicago, are reported to have provided accommodations for the treatment by the Pasteur method, of patients suspected of hydrophobic exposure.

— An unusual prevalence of typhoid fever is reported in the southern district of Chicago, which is attributed to the condition of the drinking-water. The initial cases of the epidemic appeared a few days after a big storm which flushed the sewers, and, it is said, sent their contents out into the crib in the lake.

— It is announced by foreign exchanges that the arrangements for the International Medical Congress in Berlin next year, which opens probably on August 6th, have been confided to Professors Virchow, von Bergmann, and Waldeyer. Invitations have already been extended to all German medical societies.

— The following interesting account of how a boy was wounded in a very critical place, and the injury was shrewdly diagnosticated and wisely treated by a medical student, comes to us in the daily press. We suppress only names.

"The boy, aged fourteen, had been fooling with another lad, aged about sixteen, who was chasing him with an open knife, and upon coming up with him, gave him a cut about six inches long by one and one-half inches deep, extending from a point opposite the upper portion of the sanctum, diagonally across the left ham, severing the glutacus maximus and exposing the glutacus minimus. Mr. ——, a student at —— Medical College, stitched the wound to the entire satisfaction of his father, who witnessed his labors. Fourteen stitches were found necessary to close the same."

— The *Chicago Herald* pictures for its readers the "Orton Madstone, which has wrought untold good to humanity. It is estimated that no less than one hundred people have been saved from horrible death through its virtues." It was found by a colored preacher in an Indian mound, was bought by a white boy for a jack-knife, and then started on its career of beneficence.

— The *New York Sun* says that twelve medical students found a suite of rooms on the top floor of an east side building, which they divided into sleeping apartments and study rooms. They were comfortably housed and excellently, though plainly fed, at a cost of $3.33 each, per week. They exchanged among themselves the costlier books of reference necessary for their studies, and organized themselves into a society. Rigid discipline was maintained, and a duty was prescribed for every hour of the day. In the evening and early morning they were regularly quizzed by one of their number specially selected each week for that purpose, upon the lessons for the coming day, and the spare hours were devoted to study and review. Among the members there were three honor men in the examinations, last spring, and there promises to be several more of the same class at the end of the winter's session.

BOSTON AND NEW ENGLAND.

— The conductors of the Old Colony Railroad are, we learn, to be given lessons in removing cinders from the eyes of passengers.

— All past house-officers of the Boston City Hospital, will remember Miss Rose McCormack, the head nurse in Ward B, and will be interested to know that on the 11 inst., she completed her twenty-fifth year as nurse at the hospital. She received a purse and many other gifts from the trustees and physicians of the hospital in recognition of her good work.

— A waitress at a restaurant in Bath, Me., was taken with some sort of a sore throat, and the fellow-boarders suspecting the disease might prove to be something which would lead to an unpleasant quarantine, urged that no doctor be called. After passing through the crisis of the disease she resumed her work at the restaurant, and was discovered distributing the exfoliation of scarlet fever among the 135 boarders.

— The executors of the will of the late Sidney Bartlett has announced the following distribution of the fund of $100,000 bequeathed to the charitable societies of Boston:

Museum of Fine Arts	$10,000
Massachusetts General Hospital	10,000
Kindergarten for the Blind	10,000
Massachusetts Institute of Technology	10,000
Massachusetts Charitable Eye and Ear Infirmary	5,000
Boston Asylum and Farm School	5,000
Boston Provident Association	5,000
Children's Hospital	2,500

Massachusetts Infant Asylum	2,500
House of the Good Samaritan	2,500
Home for the Aged Poor	2,500
Massachusetts Society for Prevention of Cruelty to Children	2,500
Boston Industrial and Appleton Home	2,500
The Sea Shore Home	2,500
Home for Aged Men	2,500
Home for Intemperate Women	2,500
Washingtonian Home	2,500
Boston Young Men's Christian Union	2,500
Free Hospital for Women	2,500
Children's Aid Society	2,500
Associated Charities	2,500
Society for Relief of Aged and Destitute Clergymen	2,500
Industrial Aid Society	2,500
West End Nursery and Children's Hospital	2,500
Convalescent Home	2,500

NEW YORK.

— Dr. George B. Upham, one of the oldest and best-known physicians of Yonkers, died August 9th.

— The American Dental Association, recently in session at Saratoga Springs, adjourned August 9th, after electing the following officers: *President*, M. W. Foster, of Baltimore; *Vice-President*, A. W. Harlan, and J. D. Patterson; *Recording Secretary*, George H. Cushing; *Corresponding Secretary*, Frederick Levy; *Treasurer*, A. H. Fuller. In the Association are now combined the Dental Association, the Association of the Dental Faculties, and the Association of State Dental Examiners; and the most important work accomplished at the meeting was the adoption of a resolution that no college should be represented in the Association that did not comply with the regulations established by the National College Association of Dental Faculties, prescribing a course of instruction of not less than three yearly terms of at least five months each. The next meeting will be held at Excelsior Springs, Mo.

Miscellany.

A CASE OF ACTINOMYCOSIS.

A CASE of actinomycosis has recently been under the care of Drs. Kneer and Conrad, of New York, with Dr. F. Lange in consultation. The patient, a German machinist, began to complain of pain and soreness in the right hepatic region in February last. The trouble having continued for some time without relief, exploration was determined upon, and this showed the presence of pus, which under the microscope was found to contain the actinomycis in abundance. One characteristic feature of the symptoms was a continuous high temperature. Injections first of boracic acid and afterwards of bichloride of mercury (1 to 2000), were made from time to time, in the hopes of interfering with the growth of the fungi, and the bichloride seemed to have the effect of bringing down the temperature considerably. Finally, however, pyæmia set in and the patient was carried off by an attack of pneumonia. At the autopsy the destructive effects of the fungus were found to be well-marked. The actinomyces appeared to have first attacked the intestinal canal and then the liver, which weighed nine and one-half pounds, and was studded with myriads of them. The greater part of the left lobe was in a gangrenous condition.

THE TREATMENT OF TABES BY SUSPENSION.

BERNHARDT (*Deutsch. Med. Wochenschr.*, 1889, No. 21, summarized in the *American Journal of the Medical Sciences*), has, during the last quarter of a year, treated 19 patients with about 200 suspensions. Most of these were tabetic patients, some of whom had received more than 20 suspensions, others between 15 and 20. By all, even the very ataxic, the treatment was well borne. Apart from the beneficial psychic effect on the patient of a new method of treatment there was an indubitable improvement in nearly every case. Some, it is true, stated that they felt no better, but in the majority Bernhardt recorded amelioration of the lancinating pains, increased ability to walk, diminution of the ataxia, increased vesical power, in some cases a decided influence on the lost sexual power, and in nearly all an improvement in the general condition.

He warns, however, against viewing this plan of treatment as a panacea for such a chronic disease as tabes is, and says that it has not yet been used long enough to permit of a final judgment on its value. It is certain, however, that it is a valuable means, though not for the healing of tabes, yet for the amelioration of many of the most distressing symptoms of the disease.

PHTHISIS AMONG THE SIOUX INDIANS.

DR. TREON, Agency Physician among the Sioux Indians, has an article on the above subject in the *Cincinnati Lancet-Clinic* for August 10th in which he says that during the three years that he has been physician at Crow Creek Agency he has entered in the Medical and Sanitary Record of his office 73 cases of consumption, 35 males and 38 females; of these 68 have died, 33 males and 35 females. Eight of this number were under five years of age. This mortality out of a population of less than 1,200 is evidently very high. The great prevalence of phthisis is attributed by the author to poor ventilation of dwellings, to the use of the sweat-bath, and to the use of tuberculous meat, uncooked. Syphilitic phthisis is uncommon; and indeed he states that, as a rule, the Sioux are now quite free from primary syphilis.

These causes, while in a large degree plausable, do not seem quite to accord with the further observation of the unfavorable effect of transportation to civilization, for example to the Hampton Institute.

Dr. Treon says, in this connection; "Sea air, in my experience, has not been beneficial to these people; but, on the other hand, rarely ever fails to hasten the fatal end in this disease. This has been satisfactorily demoustrated by sending the children of these people to Hampton, Va., to school. There are comparatively few of them who do not develop while there this disease, notwithstanding they are examined and supposed to be the healthiest subjects among them. So disastrous has the result of the change been that in many instances the people are unwilling to send their children there to be educated. I have opposed it, but for no other reason than that the change is too violent and results badly for them. I believe I speak the truth when I say there is not a sound one among them. Out of forty boys and as many girls examined at the Immaculate Conception Mission School, at Stephan, Dak., last fall — whose ages ranged from

seven to seventeen — forty-nine of them had dulness over the apex of one or both lungs, and twenty of them had enlarged lymphatics or scrofulous sores on their bodies."

THE REPETITION OF DISEASED PROCESSES AND ESPECIALLY RELAPSES.

A PAPER by Dr. H. Senator on the above most important and little-understood subject occupies the leading place in the *Berliner Klin. Wochenschrift*, No. 24, 1889. From a translation and summary of its conclusions contained in the *Edinburgh Medical Journal* for August, we make the following extract:

"There are recrudescences, consecutive or after fevers, relapses, and genuine second or more attacks. The recrudescence appears before the original sickness has reached its normal end, and therefore not after, but during the illness, and really represents only a stadium, an exaltation or repetition of isolated morbid phenomena (for example, in the acute exanthemata the rash is renewed) which have not at once reached their full development, but unfolded themselves in a fragmentary manner, and with short pauses as it were, probably because the morbid poison has entered the circulation, not in one dose but in several.

"The 'Nachfieber,' on the other hand, appears *after* the normal course of the original disease has been reached. It is a transitory feverish attack which does not present the characteristic phenomena of the original illness; more or less of fever and feverish disturbances, but without specific symptoms.

"Relapse or recidive and a second attack have not even yet been sufficiently contradistinguished. We commonly say that every renewal of the disease is owing to the renewed operation of the noxious agent which caused it at first, and in the case of infectious disease we think that a new infection has taken place from without. Even Griesinger, who belongs to our time, and was at the apex of science, considered that relapses of intermittent fever or abdominal typhus arose only through new infection from without. This view is now quite given up, save with perhaps one exception. We now generally say that if a sickness appears in a shorter or longer period after a sickness of the same nature has been passed through, and if it can be demonstrated that this second attack is the result of the penetration of the morbid germs from without, we speak of a repetition of the disease, not of a relapse.

"Gerhardt has given us a clear view and a rule by which to go in the acute infectious diseases at least. True relapses, he says, appear within a time which, when reckoned from the first outbreak, does not much exceed the incubation period plus the duration of the illness; they behave thus as if the infection from which they have sprung had been acquired during the course of the first illness; as if this has given no immunity and as if the morbid germs again ran through their developmental phases in the same body. Now, in measles, the incubation period is pretty constant — ten days — that is, till the outbreak of the initial phenomena. These usually last three days, and in the other four the rash is out and over, and desquamation beginning; so we have seventeen days for incubation and duration of illness. In Gerhardt's view we could only speak of a measle relapse, if the disease recurred about seventeen days from the beginning of the first attack. If one sticks to this it is astonishing how narrowly limited is the occurrence of relapse, and how cases which are thoughtlessly so called are not so in reality, but actually new attacks, standing in no other relation to the first illness.

"But it is questionable if even relapses, so limited, are caused by new infection from without, and whether this is their only mode of origin. Most infectious diseases, and specially the acute exanthemata, afford a certain amount of protection from a second attack, and so much the surer the shorter the time after the first illness. One may therefore reasonably doubt whether during the progress of such a disease a new infection in Gerhardt's sense could take place. Surely relapses would be much more frequent than they actually are. Every sick man could reinfect himself from his own atmosphere, which certainly infects others.

"Just as in the infected organism at a very early period, and before the disease has run its course, the poison can be efficacious as regards infection, so it can be efficient as regards its conferring of immunity. It is not impossible, but happens seldom, that during the course of an infectious disease a new infection may take place from without, but essentially this is not different from a repetition of the disease, it may be after years; but, at the same time, in common speech we call the reinfection happening after a short time a relapse, and later on a renewal of the disease.

"But there is another mode of origin of relapses: it is this. The infective germ is not incorporated anew, but a part of the original poison remains latent in the body, and only after the original sickness has run its course does it become efficacious for harm. This idea has lately received substantial confirmation from the fact that Alb. Frankel found, in an abdominal abscess of a man who had gone through typhoid with a relapse five months after the first outbreak of the disease, typhoid bacilli living and capable of development. Ebermaier has made a similar observation in a tibial periosteal abscess of a typhoid convalescent who had been free of fever for several weeks. Valentini found the same in two cases — one of periosteal abscess and one of empyema. May not the inflammatory foci which frequently 'complicate' typhoid not be of the same nature? On the ground of those observations, it is not difficult to suppose that the bacilli may again find their way into the circulation and anew excite typhoid symptoms, even abdominal ones, were they to arrive into the lymph apparatus of the bowel."

Correspondence.

CARBONIC OXIDE *VS.* ELECTRICITY.

MR. EDITOR, — A brief editorial in your issue of last week, comments upon the execution of the death penalty by electricity. Within the past year or more, considerable attention has been given to the question of substituting a better method of execution in place of the conventional mode of dangling the criminal at the end of a rope to the amusement (?) of a gaping crowd of privileged spectators.

The only substitute which has received serious consideration is electricity. Experiments have been made, and it would appear from the results that there are serious hindrances to the adoption of this subtle agent. Meanwhile it would be advisable to inquire whether there are no other agents, which are preferable, provided that a change upon the present mode is desirable.

In carbonic oxide we possess such an agent which has the property of destroying life rapidly and painlessly, when properly administered. Dr. B.W. Richardson, of London, several years since brought this method to public notice for the destruction of small, domestic animals, such as dogs and cats. He stated in an article entitled "The Painless Extinction of Life," that 7,000 such animals had thus been destroyed in London in a few months previous.

This gas may be made from charcoal at small cost, or it may be still more cheaply obtained from the street-mains of any coal or water-gas company.

Water-gas would be far preferable to coal-gas for this purpose, since it contains from four to five times as much carbonic oxide as the latter, and would be proportionably more rapid and fatal in its action, as the increased mortality from this cause in all large cities where it is used, and the inquiries reported to the Legislature of Massachusetts in 1884, have sufficiently demonstrated.

An atmosphere of 25 to 30 per cent. of carbonic oxide, as in the case of water-gas, or still better, one of 50 per cent. or more as may be made from charcoal, would undoubtedly destroy human life in less than two minutes, and without pain.

The writer has used a mixture of about seven per cent., with air, with perfect success in destroying small animals in from one to one and a half minutes without the appearance of pain.

The apparatus for an execution must be of the simplest and most inexpensive sort. A tight, wooden box, three feet square and seven feet high (63 cubic feet), a tightly fitting door, an aperture for admitting a gas pipe of liberal size (two inches in diameter), for applying a rapid supply of gas under ordinary pressure, and another smaller aperture to allow of expulsion of the air; the pipe to be connected with a steel main of larger size. If a higher percentage of carbonic oxide, or the pure gas is desired, a small charcoal furnace would be required for generating it, and storing it temporarily, as in the case of Dr. Richardson's lethal chamber.

Of this method, Dr. Richardson says: "Compared with other modes of extinguishing animal life, such as hanging, drowning, poisoning by prussic acid, shooting, stunning, the lethal method stands far ahead on every ground of practical readiness, certainty, humanity."

The advantages are:

(1) Painless death.

(2) Rapid action. In this respect its action should not be confounded with the slow action of small percentages of gas, such as is illustrated by the accidental deaths often occurring in hotels. These almost invariably happen by exposure to the gas escaping from a mere pinhole or slit in a gas-burner, which consequently forms but one per cent., or a fraction of one per cent. of the air of the apartment, and destroys life slowly.

(3) Economy. The cost of a wooden box or chamber, such as I have described is but a trifle, and the expense of 75 or 100 cubic feet of gas consumed is scarcely worth mentioning, when compared with the expensive apparatus required for an electrical execution.

A writer of a recent sensational article in a Boston daily, commits a curious blunder in proposing carbonic acid or Co_2 for the same purpose. This gas has more or less toxic qualities, undoubtedly, but when compared with carbonic oxide, it is weak and inefficient.

Very truly yours,

S. W. ABBOTT, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 3, 1889.

Cities.	Estimated Population for 1889.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2503: under five years of age 1149; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 742, consumption 280, acute lung diseases 161, diarrhœal diseases 545, diphtheria and croup 82, typhoid fever 55, whooping-cough 26, malarial fever 16, cerebro-spinal meningitis 10, scarlet fever 8, measles 7, erysipelas 3. From whooping-cough, New York 14, Philadelphia 5, Washington and New Bedford 2 each, Baltimore, Portland and Worcester, 1 each. From malarial fever, New York and New Orleans 6 each, Philadelphia and Baltimore 2 each. From cerebro-spinal meningitis, New York 3, Philadelphia, Boston, Washington, Worcester, Lowell, Salem, and Quincy 1 each. From scarlet fever, Philadelphia 3, New York and Lawrence 2 each, Boston 1. From measles, Cincinnati 4, New Orleans 2, New York 1. From erysipelas, Baltimore, Washington and Fall River 1 each.

In the 28 greater towns of England and Wales with an estimated population of 9,555,406, for the week ending July 27th, the death-rate was 21.0. Deaths reported 3850: infants under one year of age 1432; acute diseases of the respiratory organs (London) 160, diarrhœa 682, measles 91, whooping-cough 71, diphtheria 67, scarlet fever 57, fever 31.

The death-rates ranged from 10.7 in Huddersfield to 48.6 in Preston; Birmingham 22.0; Bradford 18.9; Hull 25.3; Leeds 26.1; Leicester 23.6; Liverpool 26.3; London 18.6; Manchester 25.1; Newcastle-on-Tyne 25.1; Nottingham 18.0; Portsmouth 21 8; Sheffield 23.4.

In Edinburgh 15.1; Glasgow 20.3; Dublin 24.8.

The meteorological record for the week ending Aug. 3, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps: –

Week ending	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.		Velocity of Wind.		State of Weather.[1]		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 3, 1889, TO AUGUST 9, 1889.

By direction of the acting Secretary of War, leave of absence for seven days is granted Colonel ANDREW K. SMITH, surgeon. Par. 12, S. O. 178, A. G. O., August 3, 1889.

By direction of the acting Secretary of War leave of absence for two months on account of sickness, with permission to leave the Division of the Missouri, is granted Major ALFRED A. WOODHULL, surgeon. Par. 5, S. O. 178, A. G. O., August 3, 1889.

Leave of absence for two months is hereby granted Major JOHN H JANEWAY, surgeon, with permission to apply for an extension of two months. Par, 3, S. O. 52, Headquarters Division of the Pacific, July 29, 1889.

By direction of the acting Secretary of War, First Lieutenant WILLIAM B. BANISTER, assistant surgeon, is relieved from further duty at Fort Wingate, N. M., and will report in person to the commanding officer, Fort Grant, Arizona, for duty at that station, relieving Captain Arthur W. Taylor, assistant surgeon, who upon being so relieved, will proceed to Fort Wingate, New Mexico, and report in person to the commanding officer thereof for duty at that point. Par. 4, S. O. 178, A. G. O., August 3, 1889.

Leave of absence for twenty days on surgeon's certificate of disability is hereby granted Captain LOUIS M. MAUS, assistant surgeon, U. S. A., (Fort Porter, N. Y.) Par. 2, S. O. 173, Headquarters Division of the Atlantic, August 1, 1889.

By direction of the Secretary of War, Captain JOHN J. COCHRAN, assistant surgeon, now on duty at Fort Adams, R. I., will report to the commanding general, Department of the Platte, for temporary duty with troops enroute to and at the summer camp at Fort Robinson, Neb. Upon the completion of this duty will return to his proper station. Par. 10, S. O. 180, A. G. O., August 6, 1889.

OBITUARY. CHARLES ELAM, M.D., F.R.C.P.

THE death is announced, at the age of sixty-five, of Dr. Charles Elam, "first gold medallist" in medicine at London University in 1846. Dr. Elam was a voluminous writer, and among his more important works may be mentioned the following: "Medicine, Disease and Death; being an Inquiry into the Progress of Medicine as a Practical Art;" "A Physician's Problems;" "On Cerebria and other Diseases of the Brain;" and "Winds of Doctrine; being an Examination of the Modern Theories of Automatism and Evolution." He was also the author of treatises on "Moral and Criminal Epidemics," "Civilization," "Illusions and Hallucinations," "Liberty and License in Science," "The Gospel of Evolution," and "Man and Science," and of numerous contributions to the medical journals.

DEATH.

In New York, August 12th, Dr. Alexander B. Mott, aged 63.

THE EFFECT OF THE CLIMATE OF COLORADO UPON PHTHISIS PULMONALIS, AS SHOWN BY THE ANALYSIS OF ONE HUNDRED RECORDED CASES.[1]

BY SAMUEL A. FISK, A.M., M.D., DENVER, COL.

FELLOW MEMBERS OF THE COLORADO STATE MEDICAL SOCIETY: — The time has come, which has been specified by the By-Laws and ordained by custom, for the Annual Address of your President, and it is my pleasure, as well as my duty, to comply with these demands.

For a long time the subject has been on my mind, and the selection of an appropriate theme has been a matter of considerable difficulty. On the one hand, I have been met by the decided objection in my own mind, to touching upon subjects that have already been so ably handled by my predecessors; and, on the other, by the desire of presenting something which would bear on its face some evidence of my own individual work and at the same time have a common interest for all.

With a view of meeting these requirements as well as I could, I have selected as the title of my address, "The Effect of the Climate of Colorado upon Phthisis Pulmonalis, as shown by the Analysis of One Hundred Recorded Cases."

In presenting this subject I feel that it should partake strongly of the flavor of having a common interest, for if there is any one thing in our surroundings that makes our work in our profession to differ from that of the thousands upon thousands of physicians, the country and world over, and which, moreover, is deserving of our closest attention, as men of some scientific attainments, it is and should be the question of the effect of this climate upon the human economy in conditions of both health and disease. It is a vast theme, fraught with no little scientific interest, affording scope enough for the ambitions of any one, and material enough for the work of a lifetime. In its broadest bearing it embraces much larger considerations than the one to which I shall limit myself, and yet, up to the present time, we of the medical profession have emphasized especially the effects of our climate in producing an arrest or cure of the disease commonly called consumption, for it has been in this direction that its effects have been most pronounced and conspicuous.

As individuals, there are and have been members of this Society who have devoted time and study to the analysis of the climate and to its effects upon this disease, and their published articles have attracted the attention of the profession generally, and have had the effect of bringing invalids of this class here by the thousands, and have resulted in the saving of thousands of lives. But, in order to give such investigations the weight that must always come from the approval of a body like our own, and, moreover, to relieve them from the elements of the personal equation which an individual's writing must always bear, this Society voted last year to entrust a consideration of this question to a "Committee of Collective Investigation," which should have power to solicit reports from the individual members of this Society and collate the same. The committee began its labors early, outlined its policy clearly, and have labored zealously, but they are not able to render any report, largely from lack of support from our own members.

It does not seem to me that in this matter there is any blame to attach to any one, nor, on the other hand, any cause to abandon our idea. This, our first attempt, should not be considered as a failure, nor should we be led to give over the project. It is one, it seems to me, which if carried out to its fulfilment, would stamp our body, in the minds of the profession the world over, as a really scientific body. Its results would be a real addition to medical knowledge to be quoted as often and spoken of as favorably as are the reports of the several investigation committees of the British Medical Association.

Let me, therefore, at this time and from this chair, urge upon you not to become disheartened, not to consider this first attempt as a failure, but rather to regard it as an experience, from which we are to profit, from which we are to devise other means by which the committee will meet with more hearty support from our members, and by which the members will find it easier to comply with the demands made upon them by your committee.

The object proposed is a mighty one, and the goal glorious. Let us push on to its achievement.

I, for one, made an attempt to comply with the request of your committee appointed a year ago, and started to collate my cases. It was not, however, until I undertook the matter that I had any comprehension of the amount of work involved, nor of the difficulty that would beset both a busy practitioner, in furnishing the data, and the committee in collating such data, if furnished. From my own experience I understand somewhat the difficulties that will beset us, for, as few as are the cases that I present as the basis of my conclusions, the task of getting them into shape is one that I doubt if I could have accomplished without the kindly aid of one of my medical students, whose services I wish to publicly acknowledge.

Out of this attempt on my part, and the understanding that the committee would be unable to make a report, grew the idea of presenting a summary of my cases at this time. In doing so I am as painfully aware as any of you can be, of the deficiencies. I regret that the number of cases is not larger, and that the time of their being under observation is not longer. They are selected cases, and do not embrace my total of recorded cases, nor, unfortunately, does my list of recorded cases contain by any means, all of the cases I have had under observation, for unless I have seen the patients at my office where my record-book was at hand, I have not been apt to take notes. But, in presenting even these few cases, I am consoled with the thought that the one thousand cases quoted by Dr. Williams in his book on "Pulmonary Consumption" are selected from the records of a busy practice of a specialist in a large city, and cover a period of twenty-two years; that my own shortcomings, as regards numbers and the time during which they have been under observation, are such as, I trust, will be remedied as years go on; that, after all, some valuable truths may be gleaned from even one hundred cases carefully recorded and conscientiously analyzed; and that I am taking what might be called "a step in the right direction," as regards the handling of this subject by the physicians that compose our Society.

[1] President's Address before the Colorado State Medical Society, at Denver, June 19, 1889.

The cases are selected, not with reference to the results being favorable or unfavorable to our climate, but because I have been able to see them frequently enough to judge somewhat of the effects of our climate upon their trouble, and to follow the progress of their disease.

Inasmuch as my only aim is to show the effect of our climate upon this disease, pulmonary consumption, it is evident that I could call to my aid only such cases as I have been able to follow for some time, so as to know whether they were benefited or injured by a residence in our climate, and to point out, if I can, the elements in these cases which tended to produce the one or the other effect.

I am not able to follow the classification of Dr. Williams in tabulating my results, for his first broad class of "well" patients I prefer to class as "much improved." I have seen, and had under my care, patients who have been pronounced well, or at least they have told me that they have been pronounced well, by other physicians, — not in this country, however, — and been dismissed as well from sanatoria, in whom cough and expectoration still persisted, and in whom there have been pronounced physical signs.

I have preferred to classify my list as

(1) Much Improved. This includes those spoken of by Dr. Williams as being able to follow their occupations without any recurrence of their former symptoms, and others, who, though still carrying some evidences of their disease, are able to pursue their occupations without any serious inconvenience. In the broadest sense they have all been much improved by their residence in Colorado.

(2) A second class I have called, Somewhat Improved. Here I have placed those who have shown improvement, — but not up to the first class. It embraces some who, after making very considerable gains in this climate, have considered themselves able to return to their homes. Others, who are in the chrysalis state, in process of formation for the first class. And still others, who, though improved in their condition on arriving in Colorado, and who, though able to work have, nevertheless, to use precautions and limit their exertions (Dr. Williams's second class).

(3) The third class, are the few who have not done well here, largely, I think, through some imprudence of their own, but be that as it may, they are actually in a worse condition than when they arrived.

(4) Those who have died. My first class numbers 50 % of all cases; my second, 17 %; my third, 7 %, and my fourth, 26 %. If now we make the broad distinction in these cases between those who have been benefited and those who have not been benefited by coming to Colorado, we can class the first two divisions as one, and the last two as one. From this we learn that 67 % of my cases have been benefited, and 33 % of my cases have not been benefited by coming to Colorado. That is, that benefit may be expected in two out of three cases that come here — taking cases as they run. This is not an altogether fair statement of the case, either, for of those in the second half I can recall a good many instances where some imprudence has made all the difference between progress and retrogression, where I think it is fair to say that an arrest of the trouble was sacrificed to some imprudence, in no way attributable to climatic influence, and not to be regarded as an effect of climate, — such imprudence, I mean, as an excess in exercise as, for instance, a very long horseback ride, or a fishing excursion, pitching quoits, or imprudence in returning to the East when it was not advisable, or, pneumonia contracted from taking a Turkish bath. Many of these cases have occurred in persons, who up to that time, were gaining, and whose prospects were encouraging, but as the result of their imprudence fresh troubles were lighted up, hæmorrhages induced, and conditions brought about from which they have never rallied. These remarks apply to nearly every one of my third list, and fully nine in the fourth. So that while I am willing to let the statement go, as shown by my cases, that 67 % of invalids that come to this climate gain by so doing, and that 50 % make marked improvement, I yet think that these figures might be somewhat increased in favor of the good influence of our climate, if only all patients would act cautiously and with discretion, which, unfortunately, they won't; and so, as I am analyzing figures, some results have to be classed as unfavorable to our climate, where in reality they are not.

Sex. — The question is often asked whether men or women do best in this climate. I do no not know that my figures will tally with the results of other physicians in this matter, for I find that only fourteen of my cases were women. Of these fourteen, six died, and and one got worse, making a percentage of 50 % who who were not benefited. Whereas of the men, twenty died and six got worse, a percentage of only 30.2 % who were not benefited. Of the remaining seven women, who were benefited, I find that six are classed with the much benefited.

These figures would seem to show that men do better than women in securing an arrest of pulmonary trouble in Colorado, and that so far as women are concerned it is an even chance as to whether they are benefited or not by coming to this State. Even here it must be remembered, however, that with the percentage balancing, a showing of 50 % on the positive side is really stronger in moral force than the 50 % on the negative, for the question arises, what might have been the results in the case of the seven who were benefited here, had they *not* come to Colorado.

Undoubtedly most women feel the separation from home friends more keenly than most men, and are less able to stand the effects of change of surroundings and conditions, than most men; so that these forces operate more adversely in the case of women than of men, which may account, to some extent, for the ratio of percentages given above. Of the six women who died, five died within six months after coming to Colorado, and the remaining one in a year. Moreover, there are other factors operating adversely in the case of most women, of which I shall have occasion to speak presently, most noticeably imperfect digestion, poor appetite, constipation, and irritability of nerve centres, all of which, in either men or women, are most potent factors for harm in cases of pulmonary consumption.

Age. — As regards the influence of age in affecting the results of a residence in Colorado on account of consumption, I find that, of my hundred cases,

3	cases were	under	20	years	of age.
53	"	from	20-30	"	"
32	"	"	30-40	"	"
8	"	"	40-50	"	"
4	"	"	50-55	"	"

Of the three under twenty years of age, all died. Of the fifty-three between twenty to thirty years of age,

29, or 54.7% are tabled as much improved.
6, or 11.3 are tabled as somewhat improved.
5, or 9.4 are tabled as worse.
13, or 24.5 are tabled as dead.

Of the thirty-two, ranging from thirty to forty years of age,

14, or 43.8% are tabled as much improved.
11, or 34.4 are tabled as somewhat improved.
2, or 6.2 are tabled as worse.
5, or 15.6 are tabled as dead.

Of the eight ranging from forty to fifty years of age,

5, or 62.5% are tabled as much improved.
1, or 12.5 is tabled as somewhat improved.
2, or 25 are tabled as dead.

Of the four ranging from fifty to fifty-five years of age,

2, or 50% are tabled as much improved.
1, or 25 is tabled as somewhat improved.
1, or 25 is tabled as dead.

All of which goes to show that the chances for doing well are better when the patient is over thirty years of age. This, however, is not at all due to the influence of climate, as a comparison of my results with those of Dr. Williams will show, for he writes:

"The influence of age and sex on the duration of consumption may be thus summed up:

"(1) The duration is longer in proportion as the age of the attack is later, the retarding influence of age being more conspicuous among males than females.

"(2) Among the females the time of the attack is on an average, earlier than among males.

"(3) The duration of the disease is shorter.

"(4) The age reached by the consumptive females is less."

Following out these suggestions, I find that in my table of deaths the average duration of life among the females after coming to Colorado was only 6.5 months, while with the men the average was 15.7 months; that with the females three were twenty years and under of age, while the same was true of only one man. It would seem from this, therefore, that the general law, as stated by Dr. Williams, is not varied much by the climate of Colorado, and that where a fatal result ensues, the duration of the disease is shorter in the female than in the male.

Heredity. — Fifty-two of the one hundred cases report some lung trouble in the family, distributed as follows,

One or both parents affected	25
One or both grandparents affected . .	7
Uncles or aunts affected	7
Brothers or sisters affected	13
	52

Of the twenty-five whose parents were affected,

10, or 40% were much benefited by coming to Colorado.
8, or 32 were somewhat benefited by coming to Colorado.
1, or 4 was made worse by coming to Colorado.
6, or 24 died after coming to Colorado.

Of those affected through grandparents,

5, or 71.4% were much benefited by coming.
1, or 14.3 was somewhat benefited by coming.
1, or 14.3 died.

The same figures and ratios hold true when the inheritance was less direct, that is, through uncles and aunts.

When brothers and sisters were affected,

3, or 23 % were much benefited by coming.
5, or 38.5 were somewhat benefited by coming.
5, or 38.5 died.

These figures go to show that in rather more than half of my cases there were some family predisposition (my percentage of 52 being in excess of Dr. Williams, where it was only 48.4 %) and that while, taking them as a body, 73 % were benefited by coming to Colorado, yet those did the best in whom the family predisposition was shown in grandparents, uncles and aunts, rather than in parents, brothers and sisters.

Hæmorrhage. — It has often been urged that high altitudes are not adapted to hæmorrhagic cases, and that, therefore, persons suffering with hæmorrhages should not come to Colorado. Let us see what lessons can be gleaned from my tables.

I find that there were forty-four cases who had had hæmorrhages, more or less severe, and more or less numerous. Of these forty-four cases I find that eleven or 25% had a recurrence of hæmorrhage in Colorado, which certainly does not uphold the statement, so often made, that this altitude is conducive to hæmorrhage. Two patients who never had hæmorrhage before coming here, had some in Colorado, and one died from the effects of his. In these cases, however, the cause was due to unusual exertion, and, indeed, many of the cases of recurrence can be traced to immoderate exercise. Of the forty-four hæmorrhagic cases I find that,

26, or 59.1% were much benefited here.
7, or 15.9 were somewhat benefited here.
2, or 4.6 were made worse.
9, or 20.4 died.

That is, 75% were benefited, and 25% grew worse or died. This certainly does not uphold the idea that Colorado is not good for hæmorrhagic cases: it goes to prove, very decidedly, the direct contrary, that such cases do admirably here.

Appetite, Digestion and Bowels. — These elements I have regarded as of the greatest importance in estimating the probabilities of my cases when they first come to me; and, taken with the indications furnished by the temperature, pulse and their ability to sleep, aid to form my prognosis quite as much as does the condition of the chest. For I have seen patients with consolidation, night sweats, constant cough and profuse expectoration, accompanied by loss of strength and flesh, and it may be with hæmorrhages, do admirably because they could eat, digest and sleep, whereas I have also seen others similarly affected go down rapidly because they could not eat nor digest what they had eaten, nor yet sleep. The following cases, though not filling all the requirements, will nevertheless serve as fitting examples of what I mean.

Miss ——, a maiden lady, about thirty-five years of ago, consulted me August 15, 1887. Her mother died of consumption at forty. A year previous to consulting me my patient caught cold, and in January, 1887, this was followed by night sweats, never had any hæmorrhage, but once or twice had spat a little blood. She had lost flesh, fifteen pounds from her average. She had a dry cough, accompanied by little or no expectoration. Her digestion was very bad, her appetite fair, bowels regular, and she slept poorly. The left apex was slightly dull, expiration was prolonged, and a few clicks were developed on cough. Pulse, 120;

temperature, 100°. This lady ran down rapidly, and in six months she was in her grave.

A couple of months later, namely, October 25, 1887, I was consulted by a man with the following history:

Dr. M——, age forty-three. Mother had consumption. Had pneumonia in spring of 1887, and coughed pretty constantly afterward. In August he had four copious hæmorrhages. When I saw him he had fallen off twelve pounds from his usual weight, and was expectorating a whitish mucus in moderate quantities. His appetite and digestion were first class, bowels regular, and the physical signs in his chest were identical with those described in the foregoing case. His pulse was 88, and temperature 100°. He exercised the utmost caution in regard to himself, and in the following May I allowed him to return East for the summer. Immediately on his reaching Boston he consulted one of the best specialists in this department in this country, who was fully informed in regard to his case, and he was told as I had told him, that there was a little dry crumpling at his left apex, probably pleuritic. This past winter he returned to Colorado again, more as a means of prevention than for any other reason, and to-day he is back at his work as nearly "well," I think, as it is possible for any one to be who has ever had serious lung trouble. In these two cases, which consulted me at about the same time, there were nearly identical conditions, as regards heredity and the lungs, existing when they came to me. The climate could work upon the one, for he had recuperative power. The other did not have. Her digestion was impaired, her appetite gone, and she was of a nervous type, and so she succumbed rapidly.

The citation of these two cases will probably illustrate my meaning better than figures could do. However, I am supported by the facts, for I find that, with only two or three exceptions, in every one of the fifty cases which I have classed as "much improved," the digestion and appetite are classed as "good," and bowels "regular," whereas of the twenty-six who "died," I find that the appetite and digestion were bad in sixteen, and in some of these cases the appetite was entirely gone, and in ten of the twenty-six the bowels are classed as constipated, loose or irregular.

Pulse and Temperature. — I need only adduce my figures in support of my previous assertion with reference to these factors as elements in prognosis. A rapid pulse and high temperature, especially when combined with an impaired digestion and appetite, are unfavorable symptoms.

Of the twenty-six deaths, I find that, at the date of consulting me, fifteen had a pulse beating at from 100–120–130, and a temperature ranging from 100°–102°–103.5°–104.2°. Of the remaining eleven, I have not kept records of these factors, in four cases; but of the seven that are left the records show a pulse over 100 in three of the cases, and a temperature 99.5° to 100.5° in the remaining four.

On the other hand, in the fifty cases tabulated as "much improved," I find only seven where the pulse and temperature were each over 100°, the highest pulse being 116 and the highest temperature 101°; of the remaining the pulse would range from 80–96, and the temperature would be normal or ranging from 99°–100°.

Condition of the Lungs. — I approach this subject with hesitancy, because I feel, as Dr. Williams expresses it, that "the classification of the conditions of the lung, consolidation, softening and excavation, into first, second and third stages, is open to objections, because such stages are not always well-defined, it being difficult, sometimes impossible, to distinguish between the end of the second and the beginning of the third, and again, various parts of the same lung may be in different stages." I also feel a hesitancy because I know that I have, at times, found undoubted signs, when others, whose diagnostic powers I highly respect, have failed to find them, and *vice versa* the tables have been similarly turned on me.

I prefer, therefore, to classify my cases somewhat differently, more as regards the extent of tissue involved than as regards its stages.

Where only a small portion of one lung is involved, for example, one apex, or where it may be that both apices are but slightly involved, for example, prolonged expiration at one; heightened percussion note, prolonged expiration and a few fine râles produced by cough with deep inspiration at the other; or further when the trouble, as sometimes but rarely occurs, is found in a portion at the base, such cases I prefer to classify as "having slight trouble."

Where the disease has progressed further than this, involving the whole of one lobe, or where, as frequently happens, râles are to be heard in two separate lobes, and yet softening has not taken place, I shall call such, "marked trouble."

Lastly, where the dulness has become very marked over one or more lobes, and this is accompanied by tubular breathing, marked bronchophony and râles of various sorts, even though I cannot positively diagnosticate cavities, as I am indeed very slow to do, I prefer to classify such cases as, "considerable trouble."

Consulting my tables, then, with reference to these distinctions, I find that of my fifty cases recorded as "much improved," the trouble could be classed as slight in thirty-four, marked in fifteen. The one remaining case consulted me four years after coming to Colorado, and I was not then able to detect any physical signs which would indicate the nature of his original trouble.

In the next class, of those "somewhat improved," I find four in whom the trouble was slight, thirteen in whom the trouble was marked.

In the next class, or those who are worse off than when they came, I find, that when they came, four could be classed as slight, three as marked.

And of the twenty-six who died, four could be classed as slight when examined, four as marked, and eighteen as considerable.

The conclusion to be drawn from these figures then is, that the most favorable cases for Colorado, as far as the condition of the chest is concerned, are those in the early stages, when the disease has not made much progress.

Later on, when perhaps they have reached the so-called second stage, they may be sent, with the hope of getting some improvement; but when the disease is very considerable, especially if the condition be marked by impaired appetite and digestion, and by hectic and rapid pulse, they had better be kept at home.

Complications. — I have had under observation, and included in my list, five cases of undoubted tubercular laryngitis. Of these, two have gained a recovery, one has made some little improvement, one has died, and the fifth was getting worse when I last saw him. One of my patients on this list has an empyæmic cavity on

the left side, where resection of the ribs has been performed, and he is around attending to his business, without any marked inconvenience. In two cases, the fibroid condition on the left side is so marked that the heart is drawn up and to the left of the nipple; but they are doing finely, and are classed as much improved. One case was attacked with acute endocarditis, some six months after coming here: he weathered the attack, and is classed as much improved.

Five of my list, I know positively, have had syphilis. Of these, two are classed as much improved, one as somewhat improved, one as worse, and one has died.

Several of my cases have been attacked with rheumatism, typhoid fever, and other complications not pulmonary; and I have not noticed that their lungs have received any additional damage from such illnesses.

But time fails me for any closer analysis of even one hundred cases, and I must stop.

The conclusions that it seems to me can fairly be drawn from the foregoing are as follows, namely: that, taking cases as they come to us, we can expect improvement in two out of three; that men do better than women, as in fact they do anywhere; that persons over twenty years of age do better than those under twenty, and that those over thirty years of age do still better; that heredity forms no bar to a person's coming to Colorado, but that the more indirect the inheritance the better are the chances; nor should a hæmorrhagic tendency debar one from coming, as such cases do admirably well; that altitude *per se* is not a producer of hæmorrhage; that the chances of obtaining an arrest of trouble are improved by the patient's possessing a sound digestion, a good appetite and a pulse and temperature not much raised above the normal; and that patients in the early stages of the disease, especially if their digestion be sound, appetite good, and pulse and temperature nearly normal, are the fittest subjects for our climate, whether they have any hereditary tendency or not.

THE CHEMISTRY OF ARSENIC.[1]

BY WILLIAM B. HILLS, M.D.,
Assistant Professor of Chemistry in Harvard Medical School.

Arsenic Acid. — This is a very poisonous compound not often met with outside the chemists' laboratory, and not likely to become the object of a medico-legal investigation. It is a white, non-crystalline, deliquescent solid, soluble in water. The solution has an acid reaction. Heated to a red heat in a closed tube it is decomposed into oxygen and arsenious oxide, the latter forming the characteristic sublimate in the cool part of the tube. It is only with great difficulty that it is completely volatilized. It responds to Marsh's test, the reduction test previously described, and Reinsch's test provided the solution is sufficiently acid. There are also special tests for arsenic acid, some of which are important inasmuch as they are made use of for the purpose of estimating arsenic quantitatively.

The arseniates of sodium and potassium are much used, especially the former in the processes of calico printing. They are white, non-volatile, deliquescent salts, soluble in water. They have only rarely given rise to poisoning. They respond to the tests for arsenic acid, as well as to those for the constituent metals.

Sulphides of Arsenic. — Arsenic disulphide occurs native as realgar. It crystallizes in more or less translucent prisms which have an orange-yellow color and a resinous lustre. The commercial product is an artificial sulphide made by subliming a mixture of arsenical pyrites and iron pyrites. The product is then melted with arsenic or sulphur, according to the shade of color desired. This artificial product is amorphous, red and opaque. Its composition is variable. It usually contains free arsenious oxide. It was formerly used as a pigment. Mixed with lime it is employed in tanning for removing the hair from skins. It is a constituent of Indian or white-fire, which is used for pyrotechnical purposes.

Arsenic trisulphide, which is known under the name of orpiment or yellow sulphide of arsenic, occurs native in translucent, lemon-yellow colored prisms. It is obtained pure by passing sulphuretted hydrogen gas through a solution of arsenious acid or of an arsenite acidified with hydrochloric acid. This compound is occasionally found in the œsophagus, stomach, or intestines of persons poisoned with arsenic, as a result of the sulphuretted hydrogen, formed during decomposition, upon arsenic present in these organs. The commercial product is prepared by subliming pulverized arsenious oxide and sulphur in the proper proportions. It is, as thus prepared, a mixture of arsenious oxide and sulphide, and is very poisonous by reason of the former constituent. It was formerly much used as a pigment under the name of King's yellow, but is rarely used as such at the present time. It is used in calico printing and dyeing, especially for the reduction of indigo; mixed with lime it is used in India as a depilatory.

The sulphides of arsenic are insoluble in water, (any oxide present, however, is dissolved by water.) They are soluble in alkaline hydrates and are reprecipitated from these solutions by an excess of acid. They are converted by nitric acid to soluble arsenic acid. They are distinguished from nearly all red or yellow inorganic compounds by their volatility. They respond to the reduction test for arsenic (with sodium carbonate and potassium cyanide) and are thus distinguished from all red or yellow colored compounds.

Arseniuretted Hydrogen. This is a colorless gas with a peculiar and extremely disagreeable odor. It is the most poisonous compound of arsenic. Prepared by dissolving any compound of arsenic with a metal in dilute hydrochloric or sulphuric acid; or by bringing any soluble compound of arsenic in contact with nascent hydrogen. It is of especial importance in its chemical relations, since upon its formation is based Marsh's test for arsenic. Poisoning by arseniuretted hydrogen has hitherto been accidental: either the result of inhaling the gas in the laboratory, or of inhaling hydrogen made with arsenical zinc or arsenical sulphuric acid; or of inhaling the gases evolved in certain manufacturing or mining processes.

MEMORANDA RELATING TO ORGANS AND SUBSTANCES SENT FOR ANALYSIS.

The organs which should be submitted to chemical analysis in a case of suspected arsenical poisoning are the following: stomach and intestines with their contents, liver, kidneys, spleen, brain and heart. Any urine remaining in the bladder should be saved, since it is with the urine chiefly that arsenic is eliminated.

[1] Concluded from page 155 of the Journal.

Medicines administered during life, suspicious chemicals, suspected articles of food and drink, the vomitus, fæces and urine, if any, voided during the attack, must also be secured. At the autopsy the organs should be placed for examination upon plates which have been thoroughly cleaned by the medical examiner himself. Special care should be taken that they are not brought in contact with undertaker's paraphernalia on account of the danger of absorbing some disinfecting fluid containing arsenic. If the stomach and intestines are opened, care should be taken that the contents are not lost, since the examination of the latter by the chemist is often of great value. If the interior of the stomach or intestines is washed, the wash-water should be saved, for it may contain solid particles of the poison removed from the mucous membrane. The organs should be sent to the chemist in perfectly clean glass jars, each organ in a separate jar, and the latter should be closed with glass and not metallic caps, carefully sealed and labelled by the examiner. They should be sent to the chemist by a messenger, or preferably two messengers, to diminish the danger of loss of identity through the death of a messenger. Above all, they should not be sent unsealed by express since their identity is thereby lost. The organs while in the possession of the examiner or messenger should never be left in any place to which others have access. No preservative should be employed. The use of such complicates the analysis, and renders an analysis of the unused portion of the preservative absolutely essential in case any poison is detected. It is a wise precaution, in cases which are likely to result in a trial for murder, to divide each of the organs and submit the separate portions to two chemists; 1 for the purpose of confirmation of results if such is desired; 2 that in the case of the death of one chemist the results of the analysis may not be lost. A frequent error in cases of suspected poisoning is that of sending the stomach alone for analysis, in the belief that if poison has been administered it must necessarily be detected in the stomach. This is a mistake; for the poison may have been entirely removed from the stomach by vomiting or absorption, so that it can no longer be detected there, while its presence is readily determined in the blood and solid tissues. This is likely to be the case if the patient has survived the administration for many hours. A mistake is sometimes made in sending a small portion of some one organ for analysis. If the amount of poison present is very small, the analysis under such circumstances may be wholly negative. The whole of each organ should be submitted for analysis. The importance of the chemical analysis of the vomitus and urine in cases of suspected arsenical poisoning should never be lost sight of. Arsenic usually provokes violent vomiting, and it may happen that the poison is wholly removed from the stomach so that none can be detected in this organ after death. If the patient survives a week or more, all the poison absorbed may be eliminated, so that after death none can be detected in any of the organs. In such a case the analysis of the vomitus might be of great importance in the way of establishing the fact of poisoning. The examination of the vomitus is further important, since, if the poison has been taken in the solid form, it may enable the chemist to determine the exact compound taken, a fact which cannot be established after the poison has been absorbed, excepting in the case of Paris green poisoning.

The examination of the urine passed during life is especially important, for the urine is the chief channel of elimination and the detection of arsenic in this secretion is a positive proof that arsenic has been absorbed into the system and is in process of elimination. The examination of the vomitus and urine thus afford the best means of establishing by chemical evidence during the life of the patient the diagnosis of arsenical poisoning.

QUESTIONS LIKELY TO ARISE IN CONNECTION WITH ARSENICAL POISONING.

(1) The question is always asked in trials for murder by poisoning with arsenic, if the quantity detected in the body is sufficient to cause death? the feeling being quite general that the evidence is defective if the answer is in the negative. The arsenic found in the stomach and intestines however, if any, is not the arsenic which has caused death. It is simply that which is left after the absorption of a certain amount, and the loss, in most cases, of a certain amount by vomiting and purging. It, therefore, furnishes no clue to the amount actually taken, which is the more important question. If a large quantity is found in the stomach and intestines, it is, of course, evident that a large quantity must have been taken. But a half-grain detected in the stomach may be the residue from a small or a very large dose. Neither does the quantity extracted from the organs ordinarily submitted to the chemist furnish any definite clue to the actual quantity taken. If several grains are isolated, a large and fatal dose must have been taken. But a small quantity may represent either a relatively small or a relatively large dose. For in the latter case much must have been thrown off by vomiting and purging and thus have escaped absorption; and much may have been removed by elimination if the patient has has survived a few days. Moreover, the chemist never isolates all the poison contained in the body, for he subjects to analysis only a small portion of the body, all parts of which, as a rule, contain more or less arsenic. The quantity isolated is, therefore, only a part of that actually taken, and does not necessarily bear any relation to the latter. Finally, we do not know what quantity of arsenic must necessarily be absorbed to cause death. We know what amount is *ordinarily* fatal. But just as this may vary widely in different cases, according to conditions all of which are not understood, so the amount actually necessary to be absorbed to produce a fatal effect probably varies in different cases. In any case the detection of *any* quantity of arsenic over and above insignificant traces is sufficient *chemical* evidence of poisoning. Of course if the amount of arsenic detected is small and *symptoms and appearances are wanting or doubtful*, it may reasonably be suggested that such arsenic may be the remnant of medicinal application, or that it may have been introduced by exposure to arsenical papers or fabrics.

(2) The question is usually asked, "Can you tell if this arsenic was taken into the system before death or introduced after death?" The answer is, "No." The experiments of numerous investigators have proved conclusively that arsenic, injected into the mouth, rectum, and other parts of the body after death, is, by the process of diffusion, carried sooner or later to even the most remote parts of the body, as the brain. It may be suggested that the symptoms in any given case

may aid us in forming an opinion, but it must not be forgotten that there are diseases in which the symptoms closely resemble those of arsenical poisoning.

Professor Reese has suggested that the detection of arsenic in the urine might be regarded as evidence of ante-mortem poisoning, as it is hardly probable that arsenic introduced after death would percolate through the coats of the bladder so as to contaminate the urine. But Dr. Miller shows that arsenic introduced after death into the stomach so diffuses itself as to be detected after a few days not only in the various solid organs of the body but even in the urine. Hence we cannot say from a chemical analysis that the arsenic was not introduced after death. We can *sometimes*, but not always, say (from the quantity found, if large, the distribution, or other circumstances), that it was introduced after death.

The question of the post-mortem diffusion of arsenic derives its importance largely from the practice prevailing among undertakers of injecting into various parts of the body shortly after death embalming fluids most of which contain arsenic as one of the ingredients. This practice is one which must occasionally result in defeating the ends of justice, and its regulation by legislation seems to me highly desirable.

(3) If the body has been exhumed, the chemist is usually asked if the arsenic found could not have had its origin in the soil which at times contains arsenic. It has been satisfactorily demonstrated however, that arsenic exists in the soil in a form insoluble in water probably in combination with iron. Schlagdenhauffen and Garnier [4] have further shown that if an aqueous solution of any compound of arsenic is left in contact with a clayey soil containing lime or iron at the ordinary temperature, the arsenic is gradually converted into insoluble compounds which are retained by the soil. Any arsenical compound introduced into such a soil, and subjected to continual infiltration of rain, if originally insoluble, remains insoluble: but if soluble, it gradually becomes insoluble, and at a depth of 0.6 to 0 9 m. from the point at which the arsenic is introduced, or no arsenic can be detected in the infiltered water, even after fourteen months.

With ordinary precautions, therefore, in conducting an exhumation the question cannot become a source of embarrassment so long as the coffin remains sound. If the coffin is so far decomposed that the soil has come in contact with the remains, it is, of course, possible that *traces* of arsenic may be accounted for in this manner provided the soil is an arsenical one. To meet the objection it is important in cases of exhumation that a sample of the soil above the coffin be submitted to the chemist with the organs for analysis.

(4) How long after death can arsenic be detected? If present at the time of death it may be detected for many years; fifteen or twenty at least. The possibility of the loss of arsenic after long periods must, however, be recognized. Hamburg mixed one gram of arsenic oxide with some finely divided organs and placed the mixture in a flask. He found that the gases evolved during putrefaction contained an abundance of arsenic. At the end of nine and one-half years the amount of arsenic present corresponded to only 0.551 gram arsenious oxide.[5] The odor of arseniuretted hydrogen or other volatile arsenical compounds evolved from putrefying organic mixtures containing arsenious oxide has been frequently noticed by chemists. A similar odor is frequently noticed when the bodies of those who have been poisoned by arsenic many months or years before, are first opened. This odor is not, however, *necessarily* indicative of arsenic, for it is sometimes noticeable when no arsenic can be detected.

(5) The effect of arsenic on the putrefactive process may be inquired into. In some cases of arsenical poisoning the body has been found remarkably well-preserved many years after death. To what extent this is due to arsenic is uncertain; for in some cases of arsenical poisoning decomposition has proceeded very rapidly, while the body has been found very well preserved in cases of death from other causes. We cannot therefore say that the preservation of the body in any given case is due to arsenic.

(6) May death have been caused by arsenic, and yet none be detected in the body? Yes. Death may take place within a few hours and none be detected in the stomach or intestines, on account of removal by vomiting, purging and absorption. It may be found in the stomach and intestines and not in any of the organs of the body; or it may be absent from one organ and yet present in other organs. Or it may early disappear from all. Wormley found only $\frac{1}{100}$ of a grain of arsenic in the liver of a dog that had been under its influence for eight days and then died from its effects.[6] Casper found arsenic both in the solid state and in solution in the contents of the stomach in a case in which death took place in twenty-four hours, but neither the blood nor the liver revealed its presence (quoted by Wormley). Grohe and Mosler record a case in which a child two years old died in seventeen hours from the effects of a green arsenical paint. Arsenic was found in the vomited matters, but not even a trace in the contents of the stomach and intestines, or in the spleen, liver, bile or kidneys (also quoted by Wormley). In the majority of cases of acute poisoning, however, arsenic may be detected in all the organs and tissues of the body: the liver usually containing the largest quantity of absorbed arsenic.

(7) In what time is arsenic eliminated? Elimination commences early and takes place chiefly through the kidneys: in part, through the glands of the skin, the mucous membrane of the alimentary canal, and in the bile, saliva, and tears. The time required for complete elimination appears to be, as a rule, about fourteen days; in some cases a longer period is required. Arsenic has been detected in the urine as late as six and one-half weeks after the last administration. Ludwig detected arsenic in the liver of a dog forty days after its administration. On the other hand, cases are reported in which death took place within a few days after taking the poison, and yet none could be detected in any part of the body.

— *Old Mrs. Smiley.* Next time I get took down sick, my dear, I wish ye wouldn't have that there young sprig of a doctor come to attend me. I don't go much on young doctors, no how.— *Mr. Smiley.* Well, Maria, who would you like to have me call? — *Mrs. S.* I've kinder took a notion to the doctor around the corner. I dunno much about him; but I see he's got a sign out "Veterinary Surgeon," and I think he must be a man of experience.— *Lay Exchange.*

ON SURGICAL TREATMENT OF GANGRENOUS HERNIA, WITH REPORT OF FOUR CASES.[1]

BY MAURICE H. RICHARDSON, M.D.,
Surgeon to the Massachusetts General Hospital; Assistant Professor of Anatomy in the Harvard Medical School.

THE time required for the operation of excision is short. In my two cases the actual time of applying the stitches was twenty minutes, while the whole operation from the first breath of ether did not exceed an hour. If, for any reason, more than an hour or an hour and a half is taken, I believe that the chances of recovery are very much lessened. Bearing in mind the importance of speed as well as of accurate adjustment of sutures, and that the only other thing of actual necessity is the protection of the peritoneal cavity from the introduction of septic material, all other steps in the operations should be shortened as much as possible. In my observation and experience the time lost in operation is at the beginning, where generally there is no need for careful dissection. It ought to take very little time for the exposure of the bowel, and a very little more to incise the ring and get the parts in position for careful examination, and if necessary, excision. The greater portion of the hour should be free for the crucial part of the procedure; namely, the introduction of the needle and the treatment of the mesentery. Another important point is to avoid unnecessary handling of the parts not only on account of the injury to the peritoneum, but also the loss of time. In order that no time may be lost in disinfecting, an assistant should be devoted to the constant irrigation of the parts during the entire procedure. With ordinary skill and experience the whole operation should not exceed an hour, or at most an hour and a half.

The extent to be resected depends upon the amount of gangrene. I think that an inch to the sound side of the constriction made by the ring is a good rule, provided that the mesentery to that part of the bowel is uninjured. It is certainly better to be on the safe side and take out too much rather than too little. A quick, sharp, transverse cut to the mesenteric attachment should be made with straight scissors, followed by irrigation and the immediate application of the first stitch. The mesentery is best treated by ligation and transfixion after the intestine has been severed. This makes the subsequent nutrition of the bowel more sure, and it also acts as a stay to hold the divided ends together, and takes the strain off the dangerous stitches at the mesenteric border. In my second case, I was surprised to find how little the pedicle of the mesentery interfered with the looks of the whole. It lay under the line of the suture as a small puckered knot, and offered little or no ragged surface to the opposing peritoneum. The action of the knot in drawing the ends of the bowel together and holding them in position, is certainly of great service. I was glad to see this point mentioned in some of the later authorities, for at the time I was quite reluctant to leave the mesentery in this shape.

The method of suturing is important. I believe that the interruptured suture of Lembert is all that is required. I do not believe that it is best to take the time necessary for a suture of the mucous coat, nor do I believe that a double row of stitches is required. If there is no other objection, the time spent is a sufficient one. My plan is to apply the first stitch opposite the mesenteric attachment, and from this point to work each way. If one begins at the mesenteric border and goes right around the intestine, he may not come out even at the other side. The procedure is greatly facilitated by leaving the thread-ends long, and having an assistant pull slightly on them, thus making the surface of the bowel taut, and in good position for the next stitch. I think it is also important not to have too many stitches, and not to include too much of the end of the bowel. Intervals of a quarter of an inch are sufficient, and an infolding margin of the same extent.

I have had no experience with Senn's plates or Abbe's catgut rings, but I have no doubt that in certain cases they will play a very important part in getting rid of the evils of the artificial anus.

The operation of incising the gut without dividing the ring, seems to me useless and absurd. I have never yet seen a strangulated hernia where the slightest thing could escape until the constriction had been divided.

Where the general condition of the patient is unsatisfactory, excision and suture should not be performed. Some patients, however, though they seem strong and in good condition, are not as good subjects for this operation as others apparently in worse shape. I have seen a young man die in less than twenty-four hours from a strangulation that reduced itself immediately after death, where no operation had been done, and where six hours before death the condition was as good as could be desired. In other cases there seems to be a power of resistance on the part of the patient, shown by actual improvement in constitutional symptoms after the immediate shock of strangulation has passed away. I believe that it is not rare to find cases where the condition is better after three or four days' strangulation than it is at the end of the first twenty-four hours. In my successful case of excision, the pulse and general appearance improved steadily during the anæsthesia and the manipulations of the operation, and when she was taken to the ward she had a better pulse than when we began to give ether. Another point in favor of the patient is a good family history, especially as to resistance to disease and longevity. While everything connected with the physical condition of the patient may be favorable for resection, potent objections may exist in the accessory conditions which surround the case. It should never be done unless the fullest preparations are at hand. It should never be undertaken without good assistants, proper instruments, all the material for perfect suturing, and every chance for asepsis. I do not think it should ever be done extemporaneously or by inexperienced practitioners. It is not an operation to be lightly undertaken.

The reasons why resection is, in my opinion, very much to be preferred to any other method, in suitable cases, where every condition is favorable, are: that we have in successful cases a return to perfect health in a few weeks; that we avoid the dangers and discomforts which accompany artificial anus as well as those from opening the intestine high up; and that we do not have to subject the patient to additional risks of secondary operations. The sum of the dangers of artificial anus and subsequent resection, as McCosh shows, I believe to be fully as great as that of immediate excision. Especially is this true if we add the danger from opening the small intestine near the stomach — a

[1] Concluded from page 152 of the Journal.

danger which we cannot avoid in any case where the small intestine is involved, unless we explore the abdomen so extensively in our efforts to find out, that we add enough to the shock of the operation itself, and to the dangers of infection, to overcome the very doubtful balance of chances in favor of artificial anus. Another very potent objection to the palliative operation is the artificial anus itself, with its dangers and disadvantages. We always have excoriations of the skin, and may have extensive phlegmons. In most cases we have a septic condition of the surrounding parts which may be quite as dangerous as a source of infection at the secondary operation as at the first.

The dangers of sepsis are the greatest during the operation of excision, as it seems to me. Nothing could be more septic than the gangrenous sac in my second case. Yet it is quite evident that this danger exists to a very considerable degree in any operation where the ring is incised and the bowel pulled out. I believe that the danger of subsequent infection from failure of the stitches in artificial anus is very great; and that there is the same danger in secondary resection. It is certainly a very difficult thing to make a tight joint with two intestine-ends in the middle of a straight incision. In a case reported some time ago in the *Boston Medical and Surgical Journal*, of ulcerative perforation of the transverse colon, I met with this difficulty, and the patient lost her life from giving way of the stitches and fresh fæcal extravasation. If the bowel is not sewed into the ring there is danger of retraction of the ends into the abdominal cavity, as in Pye's case referred to above.

As regards the comparative mortality from the different procedures, very little dependence can be placed upon statistics. Strangulated hernia which has existed long enough to become gangrenous, is in itself a very fatal condition. So far as I have been able to find, the first case of successful termination of gangrenous hernia at the Massachusetts General Hospital from its foundation to the present day, was the case reported in this paper. With the exception of the first case, all were treated by incision or artificial anus. Some authors place the mortality very high in the artificial anus, and others very low. The only statistics that would be of any value would be those of well-known operators of great skill, where the conditions under which the two operations were done were approximately the same. Some deductions might be drawn from a very large number of cases from all sources, where the personal equation would be lost sight of, but as yet the number of cases is too small. It should be said, however, that it seems very probable that the mortality is higher after resection than the tables of McCosh show, because there are undoubtedly more cases of successful excision reported than of unsuccessful. Cure by the spontaneous opening of the gut, though not uncommon, must be extremely rare in proportion to the total number of cases left to themselves.

In comparing the mortality of the different operators, it must not be forgotten that the percentage of recoveries from all cases of strangulated hernia not relieved by taxis, is quite small. At the Massachusetts General Hospital, in 94 cases of all kinds upon which an operation has been done, there have been 52 recoveries and 42 deaths, a mortality of 44.6. Excluding the cases which were practically moribund on entrance, the mortality would be considerably diminished. Of these 94 cases, 7 were gangrenous and 2 doubtful. All the gangrenous cases died, including the doubtful ones, except the last, treated by excision and suture.

Statistics of Excision and Suture.— Schmidt gives the mortality at 71.1. Makins collected 55 cases, with a mortality of 52.7 per cent. Reichel, 1884, collected 56 cases, with a mortality of 52 per cent. McCosh collected 115 cases, with a mortality of 50 per cent.

Artificial Anus, primary operation. — Körte gives 111 cases of gangrenous hernia treated by formation of artificial anus with 100 recoveries and 11 deaths. Another author gives 32 cases, with no deaths. Coppens collected 28 cases, 12 recoveries and 16 deaths. Schmidt, mortality of 85.5 per cent. Hermann (quoted by Haenel) 83 cases, with 76 recoveries and 7 deaths; 26 had fistula left. Weil, 15 cases, 2 recoveries with fistula, and 13 deaths.

Resection for Artificial Anus.— Makins records 40 cases, with mortality of 38 per cent. Haenel, 43 cases, 27 recoveries, 18 deaths; 37 per cent.

It seems to be the general opinion of surgeons, that under some circumstances, excision and return are justified. It seems to me that the primary operation should only be done when all the conditions are favorable. It is preëminently a hospital operation. Every appliance and preparation should be ready for its most perfect performance. It is not an operation to be recommended to the general practitioner or to the unskilful operator. It depends for success more upon rapid and skilful execution than almost any other operation. There is no doubt that in some cases the procedure is imperative where the part necrosed is too high up for the intestinal nutrition to be maintained. The difficulty, of course, is to be able to recognize this state of things. Even when it can be demonstrated that the jejunum is gangrenous, excision is not justifiable unless the patient's condition offers some hope. There is a chance that the relief of the symptoms of obstruction may be followed by sufficient improvement to make the secondary operation possible.

NOTE.— (June 14.) — The admirable papers published very recently by Abbe on the adaptability of Senn's principle of intestinal anastomosis to the treatment of fæcal fistula, either by the original decalcified bone plate of Senn or the catgut ring modification, are full of promise, though it is perhaps too early to say it will in all cases take the place of the methods considered in this paper.

RECENT PROGRESS IN OPHTHALMOLOGY.

BY MYLES STANDISH, M.D., BOSTON.

VISUAL CONDITION AFTER THE REMOVAL OF TOTAL CONGENITAL CATARACTS.

FISCHER,[1] in an article upon the visual condition after the removal of total congenital cataracts, in which eleven cases are reported similar to his own, reports a case from the clinic of Professor Schoeler. Patient was a girl, aged eight, who had complete soft cataracts filling the area of each pupil. Pupil action, projection and light perception were good. There was no strabismus and no nystagmus. Both lenses were removed at the same time.

On the eighth day the pupils were free, media clear and each fundus was healthy. The bandage was discarded and patient for first time in her life was able

[1] Klin. Monatsbl. f. Augenheilk., December, 1888, p. 461.

to see. Placed back to the light she opened her eyes freely and directed them properly, when her attention was sufficiently excited. With bright and shining objects both eyes fixed properly without oscillation, but very soon the effort of attention ceased and movements from side to side began. Various things, such as an apple, plum, bread, fork and her own doll were placed before her, but she recognized none of them till she touched them with her fingers. She watched attentively the movements of a large cat, but had no idea what the appearance meant until the touch of her fingers explained it. On the third day when shown the same objects as on the previous day she failed to recognize any of them, and when told to select from similar series in her lap, a thing like the one held before her, she made great mistakes as to size. Several colors were recognized and named correctly. Moving about the room, she walked against every piece of furniture in her way. When taken into a garden, stood astonished before a tree. At the end of the third week, she had learned to recognize common objects about her and to play freely with other children, and was beginning to puzzle out the meaning of pictures of things already known to her in reality.

In summarizing the reasons of these observations, the writer emphasizes the statement, that in regard to the sense of form, the child was completely blind, and, whereas in regard to direction and to a lesser degree distance, there was already a certain degree of development.

ELECTRIC OPHTHALMITIS.

The effect of the electric light upon the eye has been written upon by Terrier [2] and Maklakoff,[3] and from a summary of the publishing cases, the symptoms would seem to be about as follows:

In mild cases discomfort and pain resembling that produced by a foreign body beneath the lid begins a few hours after exposure, together with a slight swelling of the lids and increased flow of tears. The conjunctiva is injected and œdematous, œdema being chiefly limited by the portion exposed in the aperture of the eyelids. The pupil is sluggish, fundus normal, but there are subjective sensations of light and color. The symptoms may disappear completely in the course of three or four days. In severe cases there is a scotoma, relative or absolute, covering the fixation point and an appearance of supplementary colors. After a few hours, there is injection and lacrymation, followed by intense photophobia. There is great injection of the conjunctiva, especially in the ciliary zone. The pupil is contracted. These disturbances are severe while they last, but diminish at the end of twenty-four or forty-eight hours, leaving no permanent injury. Some cases, however, reported by Little,[4] showed impairment of vision with haziness round the disc two months after the exposure.

Terrier thinks, with regard to the relative power for harm of the thermic, the luminous and chemical rays, that it is the chemical rays which are chiefly harmful, and calls attention to Foucault's proposal, that the eye should be protected by means of glass tinted with uranium, which has the property of intercepting the greater part of the chemical rays.

Maklakoff states that exposure to the arc light, used for the purpose of soldering metals in a large factory near Moscow, produced on himself, in addition to the eye symptoms, smarting of the skin of the face and other exposed parts which increased in three or four hours so that the skin became swollen and painful. A few hours after the exposure a coryza began, and a little later a troublesome dry cough. From the sixth to the tenth day, the acute symptoms subsided and there remained only a slight desquamation of the bronzed skin.

NITRO-BENZOLE POISONING.

Nieden [5] reports a case of amblyopia with contraction of the fields of vision in a man twenty-six years of age, with not a very vigorous constitution who, when first seen by the author, presented the following symptoms:

Marked cyanosis of the face and mucous membrane of the lips, enlarged dark veins on the bulba conjunctiva. His eyes were dull and the expression anxious, breathing labored, pulse thready and irregular, 148 to the minute. An odor, not unlike that of bitter almonds was noticed in the patient's breath. Auscultation and percussion revealed normal condition of the lungs. Area of cardiac dullness was not increased and there was a systolic murmur. Liver enlarged and tender. Spleen slightly enlarged. Urine normal. V. O. D. and O. S. $= \frac{1.0}{20.0}$. Fields of vision upwards, 30°, downwards, 20°, outwards, 25°, inwards, 35°. Field for blue smaller than that for red. Ophthalmoscopic examination: media clear; retina and papilla, marked venous congestion; papilla, clear except a small sector of the border of the lower disc-sight, where there was a patch of exudation surrounding a vein; no hæmorrhages.

As the patient was employed in the manufacture of the explosive compound, nitro-benzole or robusit, and toxic symptoms came on after he had been engaged in this work a few months, his condition was attributed to nitro-benzole poisoning. Having abstained from work and been given cardiac tonics, he improved rapidly. His eye symptoms improved more gradually than the others. No improvement in sight for one month, but in six weeks he was able to do his work. The exudation in the right retina became absorbed, and the venous turgescence disappeared at the same time with general cyanosis.

In the manufactory from which Nieden's patient came, in the space of twelve months the large proportion of twenty-five out of thirty-three workmen had suffered more or less severely. No fatal cases occurred, although Elerburg [6] says that 34 % of the cases are fatal.

EYE INJURIES IN THE FRANCO-PRUSSIAN WAR, 1870–1871.

The Army Medical Department of the Prussian war-office has presented in Vol. III of the "Army Medical Reports," a report of the injuries of the eye in the German Army during the war with France in 1871.[7] This report coming at a much later period, is naturally much superior to that in "The Medical and Surgical History of the War of the Rebellion."

In a statistical presentation of the report, it is shown that during the war of 1870–71, injuries of the eye occurred 786 times, being 0.79 % of the whole number

[5] Centralbl. f. Prakt. Augenheilk., July, 1888.
[6] Handbuch Offent. Gesundheits., Bd. II., p. 535.
[7] Abstract. In Centralbl. f. Prakt. Augenheilk., Oct., 1888, p 309.

of injuries, and 7.8% of the head injuries. Affection of the vision after brain injuries were met with in seventy-four cases; this is 0.7% of the head injuries. The left eye was injured more frequently than the right, there being 317 injuries of the right and 374 injuries of the left eye and 76 in both eyes. Further analysis shows that 313 injuries were caused by bullets, 197 by shells, 3 by blows and 25 by thrusts. The shell injuries were on the whole less serious than those effected by bullets. The eye was destroyed in 62% of the latter and 36% of the former. The probable explanation of this is, that the bony surroundings of the eye afford better protection from fragments of shell than from bullets. On the other hand, contusions of the eye by bullets were two in number against sixty-five by fragments of shell. The injuries were divided among the different structures of the eye according to the following percentages:

Injuries of the sclera and conjunctiva, 3%; cornea, 7.7%; cornea and iris, 9.3%; iris, alone, 7%; lens alone, 5%; vitreous, 3.3%; retinal and choroidal hæmorrhage, 3%; rupture of the retina and choroid, 12.3%; separation of the retina, 9.3%; inflammation of the membranes of the eye, 15%; changes in the papilla, 10.7%; loss of sight from various causes, 22%. Injuries of the anterior portions of the eye were, in many cases, not followed by loss of the eye itself. Various noteworthy cases are reported; one in which hæmorrhage in the vitreous was caused by the atmospheric pressure of a discharge close to the left temple. Detachment of the retina followed. In eleven cases, the injury was attributed to the passage of a missile close to the eye without touching it. Among 69 injuries in the eye from bullets coming from one or the other side, the temple wall of the orbit was perforated in 34 cases, the nasal wall in 15, the roof in 15, the floor in 5. Two eyes were destroyed by shots from behind. In 28 cases both eyes were injured by bullets and in 9 of these both eyes were immediately destroyed. In many cases bullets were split or shattered by striking upon the margin of the orbit or upon the bridge of the nose. Many injuries were caused, not by the missile itself, but by other bodies striking against the eye, that is, stone, sand, spectacle-glass, etc.

No case of loss of sight due to copious loss of blood, is recorded throughout the campaign. Partial detachment of the iris occurred both at the immediate point of the injury and at the opposite side of the circle. Retroflection of the iris was observed in two cases.

In regard to the sympathetic affection of the second eye, 99 cases are recorded, but in many of these the diagnosis is somewhat uncertain. In 51% of the cases of supposed sympathetic affection, there is no record of any but subjective symptoms. In 17.4% there was inflammation of the conjunctiva; in 18.5% affection of the anterior portion of the eye and in 13% affections of the fundus. Enucleation was performed 23 times for the relief or prevention of sympathetic inflammation. In six of these cases, five of which were operated on within ten days of the accident and one seven months after, the uninjured eye was healthy; in five it improved after enucleation and in twelve the operation had no beneficial effect.

Of all injuries that destroyed the eye, left a foreign body in it, or set up a cyclitis, 56% are said to have set up sympathetic ophthalmia. Panophthalmitis appears to have caused sympathetic inflammation as often as any other form of traumatic inflammation. Injuries which immediately and completely destroyed the eye caused sympathetic ophthalmia in 62.7% of the cases. The inflammation most often appeared in the second six months after the injury. Probably the most startling portion of these statistics are those which relate to sympathetic ophthalmia.

AMAUROSIS WITHOUT OPTIC NEURITIS IN A CASE OF CEREBRAL TUMOR.

J. Hutchinson Jr.[8] reports a case of amaurosis without optic neuritis due to a cerebral tumor. The patient was a young laborer aged twenty, a bricklayer by trade, said to have been healthy till the spring of 1888, when his health began to deteriorate, and he became worse day by day. He noticed also some general weakness, became more tired than formerly, and, after a time, the eyes and head began to ache. At first intermittent, the headache became almost constant, and on June 25th the loss of sight, which affected both eyes, had so advanced that "he could not see to read large type, even when held close to the eyes." "The tops of the eyes ached"; and on June 30th he vomited once. He was thought to have tobacco amaurosis for the following reasons:

(1) The failure had been gradual, and was wholly unaccounted for by anything seen in the fundi. Both eyes were emmetropic.

(2) When tested by the perimeter, central scotoma for red and green was made out.

(3) He stated that he was in the habit of smoking about one-half an ounce of shag daily.

On investigating the case, it seemed improbable that it was really one of amblyopia. His age was much against him, and there was some evidence of mental deterioration. In addition to his complaint of headache and loss of sleep, the patient was liable to break into causeless laughter; he had a heavy and stupid expression and answered questions in a slow and rather imperfect manner. The pupils were large, and acted very slowly to light and accommodation.

The patient was admitted to the London Hospital on the 15th of September, and died three weeks later. Headache was constant to the end, but there was not the slightest evidence of neuritis and only occasional vomiting and nausea. Post-mortem examination was as follows:

Viscera healthy, with the exception of the brain. A large, soft glioma involved the apex of the right temporo-sphenoidal lobe, and reached across the middle line in the interpeduncular space. "On examining the brain more closely, it was found to be too soft to allow the exact limits of the tumor to be made out, but the growth had penetrated somewhat deeply to the right crus cerebri at the base of the brain; it extended over an area about as large as the palm of the hand and about one-half an inch in depth." The optic nerve and the posterior halves of the globes were removed and sections made involving the optic papillæ, within tranverse sections of the optic nerves both near to the eyes and towards the chiasma. The results showed that the nerve in the transverse section was equally affected throughout. The peri-neural sheath was filled up with small, round cells and delicate connective tissue, which, no doubt, consisted of prolongations of the gliomatous structure downward from the base of the brain toward the globes. Immediately behind the

[8] Royal Ophthalmic Hospital Reports, January, 1889.

lamina cribrosa was also a similar infiltration, the papilla itself, however, being quite normal. In the interstitial bands there was little evidence of change, nor could there be said to be any true neuritis.

Looking at the slight character of the changes present, it seems most probable that the amaurosis was due to the involvement of the optic chisma or tracts in the growth.

According to Annuske and Reich, papillitis is absent in only about 4 % of the total number of cases of cerebral tumor. It would be of interest to know in what proportion of 4 %, amaurosis was present without changes visible to the ophthalmoscope.

OPHTHALMIA MIGRATORIA.

Deutschmann[9] has been repeating Gifford's experiments (formerly reported in these papers) of injecting India ink into a rabbit's vitreous. Gifford traced the pigment subsequently along the central vessels passing with them out of the opticus thence back to the apex of the orbit. Deutschmann's results agree in part with Gifford's, but he also found the pigment in the sub-vaginal space close to the globe; it reached this space either by passing along the radiating vessels in the opticus, or by getting caught in the descending lymph stream at the point where the central vessels leave the nerve, and it gradually left the vessels after they had reached the orbit, so that none could be traced to the apex of that cavity. By injections into the orbit itself, he found that the pigment passed downwards and inwards between Harder's gland and the infra-orbital gland along the membrane orbitalis and that afterwards it passed through a fissure at the inferior border of the orbit and spread itself on the surface of the maxilla, but the pigment did not pass out of the orbit into the cranium. If it did in Gifford's experiment, it could not have been free pigment.

This experiment shows that the lymph stream in the inter-vaginal space runs toward the eye-ball and then passes partly into the orbit along the central vessels and partly into the supra-choroidal space, whence it gets under Tenon's capsule along the vasa vorticosa and so into the orbit. A third stream passes through the dural sheath into the supra-vaginal space and so into the orbit. Gifford's views are essentially the same. Deutschmann then submits Gifford's pathological experiments to a detailed criticism and concludes that Gifford has in no one of his three successful inoculations demonstrated the passage of microbes from the orbit into the cranial cavity, but that his experiments tend to prove that they pass from eye to eye, along the inter-vaginal space.

Deutschmann has obtained twelve positive results from thirty-four inoculations and in the successful cases has traced the micrococci from the vitreous along the central canal of the opticus accompanying the vessels, while the latter were in the nerve. Further back the collections of cocci were to be found in the inter-vaginal space of the nerves and the pia-mater of the chiasma, but hardly any colonies were detected in the orbital tissue itself. The experiments seem to have been restricted to rabbits.

Bacilli and cocci affect the eye differently; the former grow more rapidly, but set up less inflammation, the latter produce dense cellular infiltration round the sheaths of the central vessels which prevents the advance of the cocci out into the orbit, as the pigment granules do in physiological experiments; they then, Deutschmann says, work their way through lymph paths up stream to the chiasma. The inter-vaginal space is the true path taken by the cocci, the optic nerve itself is only implicated secondarily. The cocci reach this space either directly from the choroidæ into the pial sheath of the opticus, or along the radiating vessels in the opticus; they may pass from the supra-choroidal space, but Deutschmann has not seen this.

Deutschmann has demonstrated that the microbes in eyes exciting sympathetic ophthalmia are veritably pathological, by cultivating them in blood serum. The cultivations produced colonies of typical staphylococci pyogenes, albus and aureus, and the cultivations produced the same malignant types as their progenitors, when inoculated into rabbits' eyes. Pathological microbes have been found by Deutschmann in the sympathizing eye in five cases, of which one, at least, has been published. Cultivations from pieces of iris or aqueous humor produced colonies of staphylococci either white or yellow and inoculation demonstrated their pyogenic character. The rarity of sympathy from suppurative panophthalmitis is not opposed to the theory laid down, for as Leber holds, the cocci may be expelled by perforation, or rendered inactive by profuse suppuration, or, as Gifford holds, the lymph paths may have been mechanically sealed up by lymph cells. Deutschmann rejects the cases of so-called sympathetic disease excited by wearing artificial eyes, as either not sympathetic at all or occasioned by some other cause than the presence of a glass eye. The occurrence of sympathetic disease after enucleation is no objection to the theory, and the fact that a certain time always elapses between the injury of the first eye and the sympathetic disease of the other, of course supports it. The time varies from ten days, the earliest time reported in any case which Deutschmann allows, to many years, in one case thirty-five. The long intervals are accounted for either by the vitality of the microbes or by subsequent infection. Sympathetic conjunctivitis described by Galezowski, Webster and Brailey, is to be rejected completely, as are also scleritis, keratitis, cataract, retinal detachment, opacity of the vitreous, and only the classical irido-choroiditis is allowed to claim the title of sympathetic inflammation, sharing the honor, however, with neuro- and chorio-retinitis, of which many cases have been described in modern times.

The operations admissible for the protection of the second eye, are enucleation, evisceration, neurotomy of the opticus, with or without resection. Enucleation is the most certain, but evisceration with disinfection of the interior of the globe, effects the same object and, with the eyes in the state of panophthalmitis, is the better operation. Simple neurotomy cannot be certain in its results and Leber has published a case of sympathy two and one-half years after resection, but resection of a 10 mm. piece of the nerve, as practiced by Schweigger, may fulfil the indications, although Clausen has published a case where sympathy followed within seventeen days of such an operation. As the most rational treatment, an early iridectomy and repeated paracentesis of the anterior chamber is proposed, mercury to be given at the same time, and corrosive sublimate to be dropped into the conjunctival sac, as proposed by Gallenga.

[9] Ophthalmia Migratoria. Sympathetic Ophthalmitis. Hamburg, 1889. Ophthalmic Review, April, 1889.

Clinical Department.

AN INTERESTING CASE OF TRACHEOTOMY.

BY O. G. PFEIFFER, M.D., DENVER, COL.

WILLIE L., four years old, had an attack of membranous croup, which advanced until tracheotomy became necessary. As my assistants did not arrive soon enough, I cut down upon the trachea, made an incision below the cricoid cartilage, and inserted the tube.

Forty-eight hours later the membrane had formed below the tube, and before a messenger could find me, the child had slowly become asphyxiated, had passed through several convulsions, was of a blue and white mottled facial appearance, and was making an occasional struggling respiratory effort in which all the muscles of the face, throat and chest joined, but which drew no air into the lungs.

At first, the frequent futility of tracheotomy in diphtheria and membranous croup was uppermost in my mind; the next instant the thought occurred, Why were not tracheotomy tubes made longer with, perhaps, a flexible rubber prolongation of the tube? Then the thought occurred to me that, as the trachea was plugged with croupy deposit, Why could not the calibre of the trachea be dilated by the passage of a rubber bougie? Meanwhile, the child was practically dead.

A small new No. 8 soft rubber catheter was hastily seized and pressed through the tracheotomy tube, and forced on down the trachea some three or four inches. It was then withdrawn. The next struggle of the child for air was accompanied by a slight squeaking noise of air sucking a little through the trachea. The subsequent efforts of the child for air were assisted by artificial respiration with such success that, in ten minutes, the child had regained consciousness and looked around. The breathing improved.

Having been so fortunate by the introduction of the rubber tube as to get a little air into the lungs, I concluded, after the child had breathed a few times, to introduce it again. This was done, and a violent effort of coughing forced out a membranous cast of the trachea, half an inch long, that had been loosened by passing the tube. In a few minutes, the boy was breathing gently and easily, had regained consciousness and recognized his mother.

During the next four days and nights this tube had to be passed down the trachea and the loosened mucus coughed up; after these four days the trachea became clear of membrane, and in three weeks the child was well.

The lesson this case teaches is, that persistent effort, even in a seemingly hopeless case of tracheotomy, may avail something, and also raises the question, Might it not be an advantage to make tracheotomy tubes longer, with a flexible rubber prolongation of the inner canula?

— Mr. Elihu Stevens, aged 101 years and six months, the oldest man in the State of Maine, died August 11th, at Belgrade, where he was born, January 26, 1788. He was the father of twenty-two children, the most of whom are now living, and his descendants in the third, fourth and fifth generations numbered three hundred and twenty-six at the time of his one hundred and first birthday.

Reports of Societies.

MEETING OF THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES W. TOWNSEND, M.D., SECRETARY.

MAY 11, 1889, the President, DR. J. P. REYNOLDS, in the chair.

DR. TOWNSEND read a paper entitled

AN EPIDEMIC OF MEASLES WITH REMARKS ON RÖTHELN.

The reader described an epidemic of 76 cases of measles many of which were mild, some exactly resembling the description given of rötheln while others were typical cases of measles. He concluded that this was an epidemic of measles as of some 73 other children exposed who did not contract the disease, 66 had had measles before, most of these in an epidemic of the year before. This later epidemic although generally of a severe type, contained one case at least which he related and which closely resembled the description given of rötheln.

At the same time that the mild epidemic was at its height a small epidemic occurred at the McLean Asylum, all of the cases being in adults and all resembling the description given of rötheln. The following conclusions were drawn:

(1) That mild epidemics of measles occur in which many of the cases exactly resemble cases described as rötheln.

(2) That in the severe epidemic of measles similar cases resembling rötheln are occasionally found.

(3) That enlarged cervical glands and sore throat are sometimes found in measles and are not always present in cases described as rötheln.

(4) That there is no distinct symptomatology for rötheln.

(5) That the strongest evidence in favor of the individuality of rötheln is the fact that previous attacks of measles or scarlet fever afford no protection from this disease.

(6) That as second attacks of measles do occasionally occur, it is impossible to make the diagnosis of rötheln, unless, as in the Charterhouse and asylum epidemics, we meet with a series of cases many or all of whom have previously had measles.

(7) That as it is impossible to say how many second attacks of measles may occur in a given epidemic, this evidence of the individuality of rötheln is made somewhat problematical, and gives rise to the question, which the author was unable to answer, Is it possible that in some epidemics and not in others measles attacks equally those who have had measles before and those who have not, and afterwards affords no protection from measles? In other words, is rötheln a mild form of measles?

DR. C. P. PUTNAM, a guest, was a thorough believer in a separate disease, rötheln, and he saw no reason why there might not be several different diseases, resembling each other in some particulars. He had seen several eruptive diseases this winter, which resembled rötheln, but which did not give rise to other cases. He thought that cases described as rötheln never gave rise to regular cases of measles, and that this was therefore an unanswerable argument in favor of rötheln as a distinct disease. He related a case of a young man whose father two weeks before had an evanescent

measles like rash but was not sick. The young man had a slight scarlet fever-like rash, and two weeks later almost every other member of the family were slightly sick with a macular and papular eruption and slight catarrh. These cases he called rötheln.

DR. BUCKINGHAM, present by invitation, agreed with the reader and said in studying the diagnosis between measles and rötheln, whether in text-books or in the reports of epidemics, we find it made in the most various and contradictory ways, some writers not entirely agreeing among themselves to base their decision wholly upon the general symptoms, such as the length of stages or the severity of the disease; expressly stating that there is no difference in the eruption. Others make the diagnosis upon the eruption alone, and either ignore the general symptoms, or even state that they are not to be relied on for differential diagnosis. Dr. Townsend has, in the speaker's opinion, rendered a service in calling attention to the differences in cases of measles, and it is not only true that cases differ in towns during the course of an epidemic, but even in the same house at the same time, and to a great degree. He does not believe it possible to differentiate isolated cases. The only proof of the existence of two diseases seems to be the occurrence of epidemics having an individual character.

There is perhaps room for fair difference of opinion as to whether this ground is sufficient or not. We should not forget that there are individual characters to certain epidemics of other diseases, typhoid for instance. Meanwhile, the practical result of the present state of knowledge should be in the speaker's opinion, the treatment of rötheln so far as isolation goes, as if we knew it to be measles.

DR. JACKSON, a guest, spoke of the importance of thorough washing and scrubbing for disinfection as preferable to sulphur fumigation.

DR. ROTCH agreed with the writer and thinks it strange that we are still as much in the dark about rötheln as we were fifteen years ago. That until a symptomatology is given distinct from that of measles the existence of rötheln is unproven. We are learning more and more that attacks of measles are not necessarily protective from other attacks. Strümpell's description of rötheln is suitable for certain cases of measles. He saw nothing remarkable in Dr. Putnam's cases and he saw similar ones in epidemics of measles.

He would like to learn how to make a diagnosis. He remains in the same position as Henoch, of Berlin, who says he does not recognize the disease, having never seen a case. Dr. Rotch had made great efforts to see cases, having gone to the northern part of this State to see what was called an epidemic of rötheln. He found, however, typical cases of measles grading off into the mild cases previously described.

DR. COTTING spoke of an epidemic occurring in 1851–52, which, with Dr. J. Homans, Sr., he had reported, the cases resembling very mild cases of measles or scarlet fever. The article was published in the *Boston Medical and Surgical Journal*, in May 15, 1873, after reading a paper by M. Thomas of an epidemic exactly similar and called by him rötheln.

DR. ROTCH said that M. Thomas has since described cases of measles at the same time with which cases occurred resembling rötheln.

DR. C. P. PUTNAM said that rötheln resembles only the exceptional cases of measles or scarlet fever. It is hardly fair to suppose that a whole family may all be affected with a mild form of disease without any severe cases. He had never known of a case where the poison of measles was carried by a third person, and said that the poison of measles died much quicker than that of scarlet fever.

DR. J. STEDMAN related a case where a child was sick with measles, and its mattress was rolled up and put in the attic. A year later another child slept on the mattress, and exactly two weeks later came out with measles. In this case the poison had been preserved by non-exposure to the air. He asked the question, How long after an attack of measles should the child be isolated?

DR. C. P. PUTNAM said that, as a rule, four weeks' isolation was long enough in scarlet fever, and ten days in measles.

DR. ROTCH thought that this depended on the individual case. The greater the dermatitis, the longer the desquamation. Measles was probably more contagious by the breath than by the epidermal scales.

DR. LYMAN said there was nothing so embarrassing as the diagnosis of these cases, and thought it was about time the profession had made up their minds whether there was a distinct disease rötheln, or not. He spoke of a case of severe measles followed in a week by a mild attack in the same patient. He also spoke of the importance of isolating mild as well as severe cases, for one may give rise to the other.

The PRESIDENT thought that we often unnecessarily alarmed society by our great care in isolating cases.

DR. ROTCH thought it was much better to protect society, and stamp out the disease, even at the expense of frightening the family.

DR. STRONG exhibited the specimens removed by laparotomy from two patients in whom the clinical and physical symptoms were almost identical, illustrating the difficulty of making a diagnosis before opening the abdomen.

I. TUBO-OVARIAN CYST: SUPPURATING, SIZE OF SMALL ORANGE.

Patient thirty years of age; married two years. For four years previously had had pain in left ovarian region, which had steadily increased during the past year. Menstrual periods were much prolonged and very painful since marriage. The patient had never been pregnant. During the past year had lost much flesh, and had several slight attacks of recurrent peritonitis. Vaginal examination showed a strongly anteflexed uterus. The left side of the pelvis and Douglas's fossa was occupied by a mass of inflammatory exudation surrounding a tensely elastic swelling of quite regular outline, immovably adherent and about the size of an orange. Before operation the diagnosis was made of a probable dermoid tumor of the left ovary, from the presence at the lower part of the tumor of a very hard mass feeling precisely like the bone plates found in dermoid tumors. The possible diagnosis of tubo-ovarian cyst was left open. Operation showed it to be the latter.

II. DERMOID TUMORS OF BOTH OVARIES.

Patient twenty-eight years of age. Having a fall five years previously, pain began in the left ovarian region, and had since continued at irregular intervals, accompanied by slight, sharp attacks of peritonitis. The patient had been married eighteen months, since

which time she had flowed excessively at each menstrual period, and was sterile. Her temperature, as taken at intervals during the three months she was under observation, varied between 99½° and 101°. She had lost much flesh. Vaginal examination showed an anteflexed, enlarged uterus. Behind the uterus, and extending on either side up to the pelvic brim, were firm, fluctuating swellings, each the size of a small orange, surrounded by inflammatory exudation, irregular in outline, immovably adherent, and on the left extending apparently along the course of the broad ligament well to the side of the pelvis. The diagnosis was recorded, of probably double salpingitis, but the possibility of ovarian cysts, simple or dermoid, was also considered. Operation proved the latter the correct diagnosis.

The two cases showed parallelism in the clinical history, of time, sterility and menorrhagia since marriage, disability, localization of pain, and recurrent attacks of peritonitis. Physically the tumors were almost identical in their site, shape, sensitiveness, immovability and size, differing only that in the one case it was single, and in the other they were double.

Dr. Strong also referred to a third case, in which he had removed a simple ovarian cyst which had developed from a prolapsed ovary, in less than three months. The patient presented no other lesion than prolapse of the left ovary into Douglas's fossa. The entire surface of the ovary could be, and was, thoroughly examined. As the patient's ill-health was apparently from general debility rather than uterine disease, no local treatment was advised. Six weeks later the ovary was found to be enlarged to the size of an English walnut, and very sensitive. Under an ether examination no irregularity in outline was detected. In six weeks from the second examination a laparotomy was performed, and an ovarian cyst the size of a cocoanut was removed. The cyst was very thin walled, and the enclosed fluid very clear. It grew from the upper free border of the ovary. The specimen, which was to have been shown, was unfortunately destroyed. The convalescence of all the patients was normal.

AMERICAN NEUROLOGICAL ASSOCIATION.

Fifteenth Annual Meeting, at Long Branch, N. J., June 26 and 27, 1889, the President, Dr. E. C. Seguin, in the chair.

FIRST DAY. — MORNING SESSION.

Dr. Morton Prince, of Boston, presented a paper on

MALARIA AS A CAUSE OF DEGENERATIVE DISEASES OF THE SPINAL CORD.

He spoke of the frequency of tabes and other spinal degenerations in cases which also presented a history of malaria. The first case he had recorded was one of locomotor ataxia with typical tabetic crises before each malarial chill. Another had gastric crises regularly once monthly, and another crises beginning with rigor and followed by diarrhœa this occurring every three weeks. The latter case had been diagnosticated as malaria by the family physician. Altogether, the author reported in detail six cases showing the coexistence of tabes with malaria, and six cases where the malarial history was associated with disseminated sclerosis. Besides these, he had notes of three other cases of multiple sclerosis, two of locomotor ataxia, and one of lateral sclerosis with a similar relation. Generally the malarial poison was present in the system previous to the development of spinal symptoms. He pointed out coincidences in the course of syphilis and malaria, such as the slowness of action of the poison and amenability to treatment; and also called attention to the relation of the syphilitic virus to tabes. He had found but little to support his etiological theory in literature. Erb, following Schulze, had stated that tabes may occur as a sequel to intermittent fever. Tuezek had proven that tabes could be caused by the ergot parasite. Many nervous disorders are undoubtedly due to malaria, such as neuralgias, anæsthesias, severe psychoses, etc. He alluded to the deposition of pigment in the brain in some cases of pernicious malaria. It would be very important for many army pensioners if it could be definitely determined that tabes and sclerosis might be sequelæ of malaria.

Dr. N. F. Brill said that his attention had never before been directed to the possibility of such a relation, but he thought the details presented were rather too meagre for an absolutely correct decision to be made in the matter. As neuritis and malaria were frequently associated, possibly some of these spinal cases might be coincident in the same manner. Both malarial and cord disorders are very common.

Dr. L. C. Gray saw no reason why the malarial poison should not cause spinal diseases. We do not yet know the exact character of the poison. But there is a sort of periodicity in many spinal and cerebral disorders, as well as in peripheral nervous affections, which is often as marked as that of fever and ague. He had noticed this particularly in intracranial syphilis. Some of these neuropathics were even relieved by quinine, as he had observed in cases of tabes. When we speak of latent malaria, and rest our diagnosis merely upon periodicity, there is danger of error. If Laveran and Councilman were right in their discovery of the malarial germ, this should be looked for in such cases as the author had described, in order to corroborate with certainty the diagnosis. Improvement or recovery under the use of quinine was no criterion.

Dr. E. C. Spitzka saw nothing in the nature of the case to forbid an etiological association between malarial and cord disorders, but he agreed with the preceding speakers that sufficient proof of such relation had not been adduced. To show an etiological significance, it was necessary to present absolute and intrinsic proof of it. If it could be shown that, as in syphilis, there were at the time of the malarial attack nervous symptoms, it would be a different matter. In the secondary fever of syphilis there was absence of the knee-jerk. Most nervous symptoms in malaria were of a neuralgic character. The anæsthesias differ from those of tabes. It had been found that pigmentary thrombosis or embolism were the most frequent causes of serious nervous disturbances in malaria. He believed, however, that like any other cachexia, antecedent malaria might predispose to spinal affections. He had observed a case of paretic dementia of the tabetic type which was probably influenced etiologically by severe malaria.

Dr. H. M. Lyman, of Chicago, could recall but two cases where it had been intimated to him that the origin of tabes had been malarial. In one he traced

the actual cause to a subacute spinal meningitis coming on after exposure to wet and cold. The other case, instead of being true tabes, had proved to be a rheumatic neuritis. He had, in his experience, seen nothing to support the idea of a malarial etiology in tabes. A complete and perfect history, together with a microscopical examination of the blood, should be required for an indisputable diagnosis of malaria.

The PRESIDENT could not recall a single case of tabes or multiple sclerosis which presented any relation to malaria.

DR. PRINCE thought there could be no question as to the correctness of diagnosis as regarded the nervous symptoms in his cases; and as to the antecedent malaria, all of his cases were men who had been in army service, and he had documentary proof of their having suffered from that poison, in the shape of government records. The really doubtful question was whether the malarial poison still existed in the system at the time of the development of the spinal disorders. In some of them there was evidence of its persistence in the shape of typical malarial rigor and pyrexia. He did not consider his etiological explanation decisive, but merely suggestive.

DR. SPITZKA thought that there were many cases of nervous disease owing their origin to exposure during the war which were contemptuously rejected by the Pension Bureau. It seemed to him that the Association ought to call the attention of the government to the great injustice which might be done.

The PRESIDENT, although once an army surgeon and therefore prejudiced in favor of the soldiers, had been on the contrary struck by the vast number of fradulent nervous cases which were awarded pensions.

Dr. W. M. Leszynsky, of New York, was then elected to membership, and Mr. Victor Horsley and Dr. David Ferrier, of London, were elected to honorary membership. The resignation of Dr. Rockwell, of New York, was accepted.

AFTERNOON SESSION.

DR. B. SACHS, of New York, reported a case of

NUCLEAR OPHTHALMOPLEGIA WITH POLIOMYELITIS (POLIOENCEPHALITIS SUPERIOR AND POLIOMYELITIS).

The relation between these two forms of disease which had been suspected by Hutchinson, Mauthner and others was proven by this case. But one other was on record, that of Seligmuller. The history of the patient was briefly that of a ptosis of the right eye gradually developed, followed after a few months by ptosis of the left eye also, and soon after a paresis of all the external ocular muscles of both eyes appeared. This resulted in almost absolute fixation of the right eye, but left a slight inward and upward movement of the left. There was immobility of the left pupil to light, but not to accommodation. The right could not be examined because of corneal opacity. During the development of this nuclear ophthalmoplegia, a subacute poliomyelitis affecting the entire right leg supervened. There was now marked atrophy of the entire right leg. The knee-jerk was lost on both sides. There were no sensory disturbances. There were no tabetic symptoms and the patient's condition was normal in all other respects. This case proved that the affection of the nuclei in the floor of the third and fourth ventricles was due to the same pathological process which gives rise to poliomyelitis when it affects the gray matter of the cord.

DR. SPITZKA said the report of the case had been so complete and there being but one other such case on record, it did not admit of either criticism or comparison. He referred to Thomsen's case of unilateral nuclear paralysis, where there was a gummatous infiltration on both sides, and the explanation of which was to him quite impossible.

DR. SACHS asked if fibres could be traced up through the ciliary nuclei.

DR. SPITZKA answered in the affirmative and made blackboard drawings illustrative of their course.

DR. W. N. BULLARD, of Boston, then presented for Dr. J. J. Putnam a skull which was a remarkable example of

HYPEROSTOSIS CRANII.

The case had been reported to the Association two years ago. The patient was a woman thirty-one years old at death. The chief symptoms were headache, broadening of the head, dropping out of teeth, loss of hearing, vertigo, beginning some years ago. There was extreme exophthalmos. There were no retinal changes. Extensive pachymeningitis was discovered at the autopsy. There was thinning and atrophy in parts of the skull. The orbital cavities were greatly diminished in size. Virchow considered hyperostosis cranii due to inflammatory changes. In this case probably the inflammation originated at the ear. Dr. Putnam had a patient now with similar symptoms, in whom the exostoses were first noticed in boyhood, and desired the opinion of members as to the justifiability of removal of certain exostoses for the relief of pain. Dr. Bullard himself thought it might be difficult to determine which of the exostoses produced the pain. Some of the exostoses were very diffuse and the operation might have to be extensive.

The PRESIDENT believed that the pain would be more apt to originate from basal lesions, possibly dural inflammation about the issuing nerves. The jaw in this case was interesting because of its senile conformation and angle, despite the youth of the patient.

DR. W. M. LESZYNSKY, of New York, read a paper entitled

SPONTANEOUS DEGENERATIVE NEURITIS OF THE BRACHIAL PLEXUS.

The patient was a laborer, age thirty-eight. He first had pain in the left shoulder shooting down the arm which was ascribed to exposure to wet. There was then no involvement of the shoulder joint and the motility of the arm was unimpaired. All the muscles reacted well to faradism, except the deltoid which was atrophied. There was no sensory disturbance, but there was pain on pressure. Gradually another muscle became paralyzed, until a large number of the arm muscles were useless. The paralysis was accompanied by pain so excruciating that the patient could not sleep at night. A feeling of numbness extended from the shoulder down the arm over the radical distribution, and a gradual anæsthesia and analgesia supervened throughout the same area. The faradic excitability disappeared, and there was galvadic hyperexcitability. Then he began gradually to improve and will ultimately recover. The case was remarkable in its severity, in its idiopathic origin, and in the escape of the median and ulnar nerves from the inflammatory pro-

cess. Not more than one case had to his knowledge been found in literature.

DR. PRINCE thought it would be difficult in the early stages of such a case to distinguish it from progressive muscular atrophy of the shoulder type. He recalled a case of his own in which there was every reason for considering it to be neuritis. It began with cramps such as are observed in writer's cramp, and it was several years before other symptoms proved the case to be one of progressive muscular atrophy. The most common cause in such cases as the author's, was traumatic arthritis, but generally the results are slight.

DR. W. R. BIRDSALL had seen this case before, and was impressed with the idea that it might be a periarthritic affection, but the author's careful study of the case seemed to exclude this. He recollected that at that time there was some anchylosis of the shoulder joint in the case.

The PRESIDENT considered the study of the differing resistances in the healthy and diseased arm made by the author interesting, and asked if any member had had experience in such measurements.

DR. GRAY had noticed much variation in resistance in many of his patients from day to day.

DR. STARR had measured the resistance in Basedow's disease, and had found it to vary within a thousand ohms in the same cases from time to time. Electricity was diffused through muscular better than any other tissue. The chief resistance was in the skin. Probably but little of the current permeated nerves, and hence alterations of nervous tissue would not have much to do with the variations mentioned by the author.

DR. G. M. HAMMOND stated that it was well-known that the resistance differs from day to day in animals. He asked if in this case it had been measured for a number of times, and was answered that eight trials had been made.

DR. BIRDSALL thought the question of resistance had little to do with our study of disease. It was easy to explain the numerous variations, by the wide differences in vascularity and moisture of the tissues at different times. It might be due in this case to paralysis affecting the physical condition of the tissues. The saturation of the epidermis by perspiration would explain the variations mentioned by Dr. Gray. He had made measurements in cases of Basedow's disease some time ago, and believed the diminished resistance found due to the moisture of the skin. It could not depend on dynamic conditions in the nervous system, but was purely a matter of physics about which there was no great mystery.

DR. GRAY said the explanation by moisture of the skin was not applicable in his cases. The differences which he had observed were not owing to the humidity of the atmosphere, although atmospheric conditions might possibly induce dynamic changes in the body.

DR. SACHS pointed out that on one day the author's case showed 580 ohms increase on the diseased side, and on another day 1,170 ohms increase on the sound side. Such variations evidently had little to do with the pathological process in the patient. Eulenburg had measured the resistances in cases of paralysis agitans and of Basedow's disease, but without any practical results. As such measurements were very complex, they required exceedingly great care.

DR. PRINCE objected to the use of the palm of the hand for precise experimentation, owing to the great variability of the thickness of the skin, and consequently of the resistance. He thought the forearm ought to be used.

DR. LESZYNSKY had not brought forward the question of resistance in this case as a diagnostic symptom. It was increased in the affected arm at every examination. With subsidence of the symptoms the resistance gradually diminished, but there was a difference between the sound and morbid side throughout the disease. As to the question of moisture, there was excessive perspiration upon the paralyzed arm, while the normal arm was dry, in spite of which the resistance was greater upon the former. He thought it better to place the electrode upon the wrist than in the hand. There was no antecedent traumatism in the case; the roughening of the shoulder joint was the result of the paralysis.

DR. M. ALLEN STARR, of New York, then presented a specimen of an

INTERPEDUNCULAR MYXOSARCOMA.

It lay in the middle cranial fossa in the median line between the crura cerebri which it separated. It extended into the lateral ventricles, separating widely the caudate nuclei and optic thalami. The patient was a male, aged twenty-one months at death. At the age of thirteen months, in October last, a lateral nystagmus had been observed in both eyes varying from time to time. Drs. Knapp and Roosa found a slight pallor of the optic discs which they considered normal. Later exophthalmos developed, gradually increasing until death. Convergence of the eyes was impossible, although no paralysis of a cranial nerve was discoverable. The reflexes of the iris were lost. Towards the middle of April this year, the child became unable to walk. The knee jerks were exaggerated, there was ankle clonus, and typical spastic rigidity. Finally the back could not be held up, and later the head could not be supported. There was gradual emaciation. There was no apparent headache. From time to time the scalp was congested. About this time the pallor of the optic discs indicated atrophy. There was no blindness, no hemiopia, no aphasia as far as could be ascertained in so young a child. Towards the middle of May, ataxia of the arms developed, but without the loss of muscular power. On June 8th, vomiting and Cheyne-Stokes respiration came on, and the child died in nine hours. The diagnosis of the tumor had been made, but the question of localization was of great interest. Nystagmus was not a localizable symptom, but had been found most freqently in lesions of the corpora quadrigemina. The exophthalmos indicated intracranial pressure; the gait disturbance led one to think of a cerebellar lesion; while the ataxia of the hands pointed to a basilar trouble affecting symmetrically either the pons or the medulla. The question of operative interference had been considered, but he had opposed that proposition because of the difficulty of localizing the tumor. The autopsy proved that the pons was not even pressed upon, and that the cerebellum was normal. There were twenty ounces of fluid in the ventricles. He would ask if there was any localizing value in nystagmus or exophthalmos, and what was the probable cause of the ataxia?

The PRESIDENT in referring to the question of ataxia recalled a case of remarkable bilateral ataxia with optic atrophy, where a large interpeduncular tumor was

found between the crura. He thought such ataxia was to be accounted for by pressure upon the motor tracts or motor nuclei. To him the most puzzling feature of Dr. Starr's case was the absence of blindness. As to the nystagmus, it had as yet in his opinion no localizing value. He had seen two cases with lesions of the quadrigeminal bodies but without nystagmus.

DR. LESZYNSKY said the child may have had only central vision which might explain the presence of nystagmus, but Dr. Starr answered that the visional fields were normal.

DR. SACHS was reminded of Meynert's case of tumor in both optic thalami with ataxia similar to that of Dr. Starr's case. He thought the thalami might have been pressed upon in the latter, but still was not sure that would cause the ataxia. He considered nystagmus very frequent in many central disorders of children.

DR. H. M. LYMAN referred to a case he had seen recently of defective cerebral development in a child where there was also nystagmus.

DR. GRAY asked how a diagnosis of intracranial tumor had been made so early in this case, and was answered that the diagnosis had not been made until all the symptoms described had made their appearance.

DR. HAMMOND thought ataxia depended upon injury to the optic thalami or corpora striatai and referred to a case of Weir Mitchell's, in which there was a remarkable unilateral ataxia with a lesion of the optic thalamus and corpus striatum upon the opposite side.

DR. LESZYNSKY saw a child several years ago with well-marked nystagmus which disappeared in the course of time. There was no discoverable cause.

The following gentlemen were then elected to active membership: Dr. C. Eugene Riggs, of St. Paul, Minn.; Dr. H. S. Upton, of Cleveland, O.

(To be continued.)

— In summing up the Maybrick case, Justice Stephen's remarks were rather severe upon "expert testimony," medical and other. He warned the jury about the uncertainty of medical science, or rather art, and reminded them of the old saying which described "a doctor" as "a man who passed his time in putting drugs of which he knew little into a body of which he knew less." He also had a fling at the experts in other fields who appear before parliamentary committees and the like. He said a man going on the stand, and "calling himself this, that, or the other, by no means qualified him to receive unhesitating belief." "A great deal of what he might call scum had to be taken off the testimony of skilled witnesses, for — of course, probably insensibly to themselves — they were apt to become advocates rather than witnesses."

— A species of fraud which it would be difficult for any "confidence man" to imitate in this country has lately been made the subject of judicial investigation in England, where a doctor has been making a practice of buying medical practices, holding them a little time and then selling out at a large premium on the strength of false representations as to their value. He bought one for £250, and sold it in thirteen months for £650. Another was purchased for £297 and one-half of it was sold to a partner for £500.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 22, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

THE INFLUENCE OF MICROBICIDE MEDICINES IN THE TREATMENT OF PHTHISIS PULMONALIS.

FOR a time subsequent to Koch's discovery of the microbic origin of tuberculosis the special attention of experimental therapeutists was directed to the various antiseptic methods which it was hoped might rid tuberculous subjects of the germs whose depredations in the pulmonary textures constituted phthisis pulmonalis. Inhalations took a prominent place; creasote, carbolic acid, sulphuretted hydrogen, eucalyptus, turpentine, hydrofluoric acid, have all had their advocates and their day. Bergeron's gaseous rectal injections of hydrogen sulphide were given with the same intent, the belief being entertained that the hydrogen sulphide introduced by the rectum would, in being eliminated by the pulmonary mucous membrane, destroy the tubercle bacilli there pullulating.

It must be confessed that the results of the germicide treatment have not been what was hoped. Experiments in the laboratory seemed to have shown that fluorhydric vapors were especially obnoxious to the tubercle bacilli. Hippolyte Martin had signalized the parasiticide effect of this acid, which in the proportion of 1 per 4000, appears to be destructive to Koch's bacillus. Jaccoud's laboratory experiments, it is true, were contradictory to those of Martin. Leiter and Garcin, subsequently Gautrelet, published papers in which the curative benefits of fluorhydric inhalations were vaunted; but other clinicians failed to confirm these results. Thus, during the course of the last year, Grancher and Chantard undertook a double series of experiments to test the value of fluorhydric inhalations in phthisis. In the first series, they came to the conclusion, "that the action of the vapors of fluorhydric acid on the evolution of experimental tuberculosis is *nil*." This conclusion was only strengthened by the results of the second series, where they studied comparatively the effects of pure tuberculosis cultures, and of cultures previously subjected to hydrofluoric

acid in increasing concentration from ten per cent. up to a state of purity.

Dr. Marcellin Cazaux, in a recent article in the *Journal de Médécine*, well sums up the present state of science, when he says that phthisis is rather a question of a particular *terrain* (culture soil) than of a bacillus. Phthisis is not like syphilis, the virus of which is capable of undergoing evolution in any soil. The micro-organism of tuberculosis does not attack all persons, it selects its subjects. The individual who finds himself in condition about normal of organic equilibrium, resists with success and *burns* the bacillus, when the latter penetrates his air-passages. For this reason, tuberculosis is the least contagious of all the microbe-diseases. In short, "the question of *terrain* [soil] is primordial and fundamental; it occupies the first place in prophylaxis and treatment, and no therapeutist can do good work in combating phthisis who does not set out from this stand-point.

Such being the case, it is evident that the first thing to do in treating phthisis is to modify the culture soil so that it will be refractory to the bacillus. Here the principal reliance must be on reconstituents and tonics. Dr. Cazaux places great importance on "superabundant alimentation, and the greatest possible quantity of pure air." Residence in the open air, when the weather will permit, and especially residence in high altitudes (from 700 to 1,600 metres), is one of the principles of successful treatment. On all suitable occasions, the windows of sleeping-rooms should be left open at night. He remarks that one will tolerate in a horizontal position, and consequently in bed, temperatures which seem severe when one is sitting or standing. Dr. Cazaux cautions against sending to elevated stations patients with advanced lesions and with fever.

The medicinal treatment, while not to be neglected, is only of secondary importance; at the same time, under the use of the classical remedies, cod-liver oil, arsenic, creasote, tannin, alcohol, one will often witness an augmentation of weight and favorable modifications in the local signs. As adjuvants, inhalations, now no longer relied on as curative, may produce some ameliorations.

In the discussion which followed the reading of Cazaux's paper (*Société de Médecine Pratique*, June 6, 1889), there was a general consensus that generous alimentation, exercise in the open air, pulmonary gymnastics in elevated regions, offer the best conditions for obtaining, if not the cure, at least the amelioration of phthisical patients. Some were of opinion that inhalations, especially of hydrofluoric acid, possess considerable efficacy, exciting the appetite, diminishing expectoration, and sometimes hæmoptysis, and promoting nutrition. In cases of early phthisis, climatotherapy, and the mineral water cure are often of great utility. The sulph-sodic mineral waters (Eaux-Bonnes), the sulph-sodic-iodo-bromureted (Guyot), and the arseniated-sodic (Bourbole), were especially commended. One speaker (Guelpa) alluded to the "astounding fallacy" of the hot-air-respiration cure of phthisis. Very rigorous experiments have proved that by reason of evaporation, the air which penetrates the lungs immediately undergoes a relative cooling, and the expired air is never 40° C. at the most, the air that enters the lungs is not raised above one degree in temperature, consequently Koch's bacillus, which is arrested in its evolution when the surrounding temperature is above 42° C., is in no way influenced by inspiration of hot air.

Per contra, in Cochin Hospital, hot-air inhalations have been tried with very uncertain results, so that Dujardin-Beaumetz is forced to tell us that we must fall back upon *sur alimentation* and hygiene. "After alimentation in importance comes climate. Oxygenation is the great point, and as much open air as possible, no matter where it is, but best when the temperature is not over 60° F. in winter." "In a word we have to confess," says Beaumetz, "that we are reduced to alimentation and respiration of pure air in this disease."

TUMORS IN ANIMALS.

TUMORS in animals, though not so common as in man, are far from being rare. A very great number of observations on the subject has been published, particularly of tumors occurring in the domestic animals. The study of such new growths offers many points of interest as to their relations with tumors in the human species in etiology, pathology, evolution and treatment. A monograph on the subject has recently appeared in the *Revue de Chirurgie*, in which Dr. Plicque has availed himself of the studies of many veterinarians to construct a most instructive article.

This article of Dr. Plicque's contains many very interesting observations and remarks, which have a more or less direct bearing upon human pathology. The importance of irritation as a cause of the so-called cancer of the lip is shown in animals. This disease, so frequent in man, is also very common in the horse and the cat, but with remarkable difference in situation. In man, the lower lip is the almost invariable site. In the horse, the disease is situated almost invariably at the commissure, the point where the bit chafes; while in the cat, the upper lip is more often diseased than either the lower lip or the commissure, that being more exposed to injury than the lower lip from its greater size and from the fact that it covers and protects the lower.

Heredity is of some importance in the etiology of tumors in animals, especially in the melanosis of the horse. Its influence is so manifest, that melanotic horses should not be employed for breeding purposes. Melanosis, when hereditary in horses, appears at a younger age than in other conditions.

Melanosis, a variety of tumor so malignant in man, is far nearer the innocent type in animals, especially in the horse. A melanotic nodule on a spot subject to irritation by harness, sometimes disappears when the harness is so adjusted as to no longer irritate the

new growth. The retrograde process has even been observed after the growth has begun to ulcerate. Other tumors, especially sarcoma and carcinoma, are often more intensely malignant in animals, especially the horse, than in man. Animals so protected as to live to an unnatural old age are especially subject to cancer. As a predisposing cause of malignant disease, Dr. Plicque believes age to be more important in animals than in man. Bouley, a French veterinary authority of experience, believes, on the ground of long observation, that dogs are doomed to cancer if they live to old age and are not killed by some acute pulmonary or gastro-intestinal affection. The cat, often cherished and kept alive when old and miserable, is also very subject to cancer in age. Statistics show that cancer is far more frequent in the carnivora than in vegetable eaters. This statement, as Dr. Plicque believes, is a capital example of a doctrine, founded on statistics, eminently calculated to deceive. The carnivorous domestic animals, cats and dogs, are preserved usually to the full extent of their natural lives, while the herbivorous horse and cow are usually killed before they have reached the extreme old age, at which cancer is most likely to show itself.

MEDICAL NOTES.

— The Pennsylvania Institution for the Deaf and Dumb and the New York Cancer Hospital are both to be enlarged.

— Among the active old men is to be classed, according to a contemporary, his Holiness Leo XIII, who is eighty-two years old, and active, robust and hearty for one of even a less advanced age, and he speaks of himself in far more promising terms than he did twelve years ago, when he told his friends it would be useless to make him Pope, for he had only a few months to live, and his appearance then did not belie his words.

— As we learn from the *Medical Record*, the German physicians have adopted a code of ethics. On June the 24th the seventeenth Congress of German Physicians met at Brunswick, and passed the following resolutions: (1) Every kind of public laudation, whether it proceeds from the physician in question himself or from others, and continued advertising in public papers are to be reprobated. (2) The designation "specialist" for puffing purposes is to be reprobated. (3) The public offering of medical assistance gratis, underbidding in concluding contracts in sick societies and the like, offering advantages of any kind to a third person in order to procure practice, are inadmissible. The designation "Klinik" and "Poliklinik" (hospital) belong exclusively to institutions which serve the purposes of instruction in connection with universities. (4) The ordering and recommending of secret remedies are inadmissible. (5) Any attempt of any kind on the part of a physician to intrude upon the practice of another is dishonorable, especially in the case of one who has acted as substitute or in consultation. A practitioner must by no means undertake the treatment of the case without the express assent of the previous physician. A specialist called in for a definite part of the treatment must strictly confine himself to that. (6) No physician is at liberty to make disparaging remarks to others about another physician.

— Dr. Rickets, of Cincinnati, in the course of a paper read before the Cincinnati Obstetrical Society on the "Abuse of Pessaries," said:

"A prominent obstetrician of Cape Town told me recently that while he was on his way to see a patient he was called in and urged to attend a lady in labor, as her obstetrician could not be found. Upon digital examination he found a large-sized Hodge's pessary, and with difficulty removed it. Finding that the presentation was a normal one, and being in a hurry, the doctor called in an American physician to attend the case, and left the house. After the birth of the child, the American physician wrote the following note to the family physician, and left the house:

"'My Dear Doctor, — Dr. S. delivered your patient of a huge Hodge's pessary, and I have delivered her of a small child.

Very truly, DR. C.'"

— London, says a correspondent of the *New York Times*, has 81 hospitals and 50 dispensaries which are supported by voluntary contributions. These hospitals contain 8,012 beds, of which 5,926 were occupied every day of last year, the number of patients being 74,316. In addition to these, 1,038,427 out-patients were treated at the dispensaries and out-service departments of the hospitals. How many recurrent cases are included in these aggregates it is not possible to discover, but the reports do not suggest that there are any, so that if the statements are absolutely correct they show that fully one in every four of the inhabitants of London receives gratuitous medical treatment when ill, a condition which at least suggests large abuse of this form of charity and want of vigilance in its administration.

During 1888 the total expenditures were (at $5 per pound sterling) $2,813,405, and the total income, not including legacies, $2,544,130; but these legacies amounted to $1,156,920 more, a total of receipts of $3,701,050. Of the regular income, $1,679,665 came from charitable contributions, $636,520 from investments, and $227,945, or 8 per cent. only, from payments by patients.

Superimposed upon the foregoing is a vast system of poor law medical relief, where the vast army of practical paupers in London are treated at an annual expense of about $300,000.

BOSTON AND NEW ENGLAND.

— At the Naval Bureau of Medicine and Surgery, bids were offered for the construction of a building for the sick at Portsmouth, N. H. Navy Yard. The lowest bid was $35,000. As the appropriation act limited the cost of the building, including furnishings, to $35,000, no award will be made.

— The Cambridge, Mass., Hospital is made residuary legatee under the will of Mary R. Popkin, of Cambridge, niece of Dr. Popkin, who was for many years a professor in Harvard College.

— Hon. E. S. Converse, of Malden, Mass., has presented to Dr. John L. Sullivan, president of the Malden Medical Society, $12,000 in cash, and a valuable lot of land off Vista Street, in Ward Three, containing four and one-half acres, for the purpose of erecting a hospital. It will be built on a hill, commanding a fine view of the surrounding country, near the Medford line, in one of the healthiest portions of the city and will probably cost when completed $40,000. The association will raise what money they can by giving lectures and entertainments the coming winter season, and it is thought that the hospital building will be commenced early next spring.

— The present week has witnessed the decease of two venerable and respected members of the medical profession, in Boston, Dr. Herman Brimmer Inches and Dr. Le Baron Russell, of whom brief mention will be found in another column. They were contemporaries. The former was a member of the Harvard College class of 1831, having among his classmates the physicians, C. A. Allen, George A. Bethune, Francis H. Gray, George C. Shattuck, and N. B. Shurtleff, besides John Lathrop Motley and Wendell Phillips, and other distinguished men. Dr. Russell graduating from Harvard a year later, was in the class with George Ticknor Curtis, Judge Abbott, Rev. Drs. H. W. Bellows and Charles T. Brooks, and Drs. Estes Howe, Stephen Salisbury and W. W. Wellington. Neither Dr. Inches nor Dr. Russell were compelled by pecuniary necessity to follow the details of medical practice, and both utilized their leisure and their wealth in works of general advantage, educational and philanthropic, for their fellow citizens.

NEW YORK.

DEATH OF ALEXANDER B. MOTT, M.D.

— Dr. Alexander B. Mott, the fourth son of the late Dr. Valentine Mott, died at his country-seat at Yonkers, on the 12th of August. The cause of death was pneumonia and he was ill only two days. He was born in the city of New York, March 21, 1826. A considerable portion of his boyhood and youth was spent in Europe, but he returned to this country to begin the study of medicine in his father's office. He attended lectures successively at the University Medical School, New York, Castleton, Vt., and the New York Medical College; and in 1850 he was appointed surgeon to the New York Dispensary. His first hospital appointment was at St. Vincent's Hospital, of which he was one of the founders, and he was surgeon to Charity Hospital for fourteen years. In 1857, he received the degree of M.D. from the University of Pennsylvania.

Dr. Mott was one of the founders of Bellevue Hospital Medical College, and was Professor of Surgical Anatomy from its organization in 1861 until the year 1872. From 1872, up to the time of his death, he was Professor of Clinical and Operative Surgery. He ranked high as a surgeon, and performed many capital operations. Outside of the profession he was well known in the community and he was one of the leading Masons of the city.

In April, 1861, he organized the medical corps of the militia regiments which were sent to the war from New York, and with the co-operation of a number of prominent ladies founded the United States Army General Hospital in New York, of which he was made surgeon in charge. In November, 1862, he received the commission of Surgeon of United States Volunteers with the rank of Major. In 1864, he was appointed Medical Inspector of the Department of Virginia, and was attached to the staff of General Edward C. Ord. July 27, 1865, he was mustered out of the service with the brevet rank of Colonel.

Dr. Mott's funeral occurred at Trinity Chapel, August 15th, and was largely attended by the public. Among those present were the Faculty of Bellevue Hospital Medical College, and members of the Old Guard, Loyal Legion, New York County Medical Association, various Masonic bodies, and of other organizations to which he belonged. Dr. Mott was a widower, and leaves one son, Dr. Valentine Mott.

Miscellany.

ACTION OF QUININE ON THE PREGNANT UTERUS.

AT a recent meeting of the Glasgow Obstetrical and Gynecological Society, (*Glasgow Medical Journal and Practitioner*, July, 1889), Dr. Robert Park read a note on "The Action of Quinine in Medicinal Doses on the Pregnant Uterus, with an Illustrative Case." Mrs. C., age twenty-seven years, three years married, never pregnant, had consulted him in August, 1886. On examination he found her suffering from retroversion of the uterus, with tender fundus. This was replaced without difficulty, and a Hodge pessary introduced, the relief from which was entire and immediate. She soon thereafter became pregnant. In August, 1887, when about five and a half months pregnant, she was threatened with a miscarriage — considerable discharge with rhythmic pains, which, however, subsided on the administration of opium, with small doses of liq. ergot. ammon.; and on the 31st of December following, she was delivered of a healthy and vigorous female child. On inquiring as to the cause of the hæmorrhage, Dr. Park could elicit absolutely nothing, except that three days previously, she had taken a dose of quinine to relieve a neuralgia. He considered that she must have taken from ten to fifteen grains, from the effects produced on the head. The patient herself stated that, soon after the singing in her ears stopped, she began to feel uneasy about the lower part of the abdomen. The argument put forward by Dr. Park in this case may best be stated in his own words. "As the quinine induced a violent and untoward uterine excitation in this case, by a dose which is a least within ordinary medicinal limits,

though inducing toxic effects in this one particular case, it must, in smaller doses have a distinct, though less obvious, action of the same kind." He believes that all the tonics which have influence over non-striated muscular fibre exert their influence over the uterine muscular system, unless and except when these are the seat of inflammatory hyperplasia.

TUBERCULOSIS AND FOOD-SUPPLIES.

IN an interesting address on "Tuberculosis" recently delivered by Dr. James Niven, medical officer of health for Oldham, before the (English) Association of Public Sanitary Inspectors, the lecturer drew the attention of his audience, says the *Lancet*, to various aspects of tuberculosis, both in the human subject and in some of the lower animals, with especial reference to their bearing on the question of public health. As regards the influence of foods in the production of tuberculosis, Dr. Niven held that every one would probably allow that milk from an animal having tuberculous udders might be infective; and, since there is much difficulty in determining when there is a tuberculous focus of disease in the udder, the milk of tuberculous cows should be always condemned. In this connection he referred to the fact that the owner of a valuable herd of cattle, on finding that a large proportion of his cows were tuberculous, withdrew the milk from the market, and used it, without previously boiling it, for the fattening of his pigs. The result was that the pigs, almost without exception, were so affected with the disease as to necessitate the slaughter of the whole stock. As to the use for food of the flesh of tuberculous animals, the question was regarded as one of greater difficulty. Observation seemed to show that the meat of tuberculous animals — and this especially in the case of chronic disease — did not necessarily convey disease and this although it is difficult to conceive how tubercle bacilli, which are liable to be scattered throughout the body by means of the blood-vessels, can fail to find lodgement in the flesh. Dr. Niven's own opinion is against the use of such flesh as food, although he admits that this by no means constitutes the greatest danger as to tubercle in its relation to food-supplies.

A FATAL CASE OF TOBACCO POISONING BY TOBACCO-SMOKE.

AN unusual case of what was really acute tobacco poisoning, although occurring in a habitual smoker, is described by Dr. B. W. Richardson, from his own observation, in the *Asclepiad*.

The patient, who was between thirty and forty years of age, was a small but well-built man, of very active habits, and reported to be exceedingly diligent and able in commercial pursuits. Previous to the occurrence about to be narrated he had been very much worried with business affairs, and had, no doubt, been trying to carry out labors which, if not beyond his own natural powers, at all events taxed them severely. He returned from business in the city of London one evening extremely fatigued, took a very slight meal, smoked several cigars and cigarettes, the precise number being unknown, and retired to bed. During the night he was heard moving about as if restless, and early the next morning rose to work. He dictated some letters and other documents to his private secretary, and declining all food, recommenced to smoke a cigar. He continued this process of smoking and dictating during the greater portion of the day, taking no food and, except a small quantity of brandy and water, no drink. In a period of less than twelve hours he had smoked forty cigarettes and fourteen full-sized, full-flavored cigars. As the evening advanced he became prostrate, excited, and restless, refusing food and only sipping at drinks. Late at night he still refused to take either nourishment or medicine. He agreed, however, to give up smoking, and he went to bed and essayed for a few hours to sleep: he could not sleep and continued excited and restless.

Early on the following morning he was seen. He was at this time half-dressed and out of bed. He was in a state of continuous muscular tremor, and when he moved across the room to reach his bed his legs seemed bent or bowed as if he were permanently deformed, which, however, was not the fact. He had evidently lost the full use of the muscles of the lower extremities, and he climbed into bed with considerable difficulty. When he reclined in the bed a continual movement of the muscles of the arms and legs was kept up, and the facial muscles moved occasionally in an involuntary manner. The pupils were widely dilated, and the eyelids were in persistent movement, half voluntary. The tongue was dry and dark red in color. The surface of the body was cool (96° F.), clammy, and perspiring. The speech was faltering and the mind uncertain. The pulse was soft, full, and feeble. Both sounds of the heart were clear, but the action was relaxed and occasionally intermittent. The respiratory sounds, at this period, were clear, but the respiratory movements were irregular and sighing. The breath and cutaneous secretion were oppressively charged with the odor of tobacco.

All further resort to the cigars and cigarettes was strictly forbidden, and fluid nourishment was ordered as freely as it could be given, together with small quantities of alcohol; it was directed that the temperature of the room should be sustained at 70° F., with free ventilation; and, in order to sustain the process of elimination, full doses of the solution of acetate of ammonia were administered every four hours. It was also carefully observed that the urinary bladder should be kept free of distension from urine, a practical point of great importance in the treatment of all forms of narcotic poisoning.

The food and medicine prescribed for the patient were much objected to by him, his mind being entirely listless and every exertion seeming to be a source of annoyance. Still, he took and retained some food, and under its influence became warmer. But as the day advanced he grew gradually more and more unconscious, the muscular paralysis increased, extending from the lower limbs to the arms; every now and then there occurred a faint general convulsion, and the breathing became noisy and embarrassed. In the evening the patient was quite unconscious; his bronchial passages were filling with condensed watery fluid; he was unusually cold; there were constant jactitating movements of the muscles, and the collapse was complete. Death took place a short time after this change. A post-mortem examination could not be obtained, but the final mode of death was evidently by asphyxia from the accumulation of fluid in the pulmonary bronchial tract.

THE FASHIONABLE CONSULTING PHYSICIAN.

THE following view of the popular consulting physician is given in *Blackwood's Magazine.*

"They sit for a great part of each day at the receipt of custom, tossing the sovereigns and shillings into the drawer, where they are decorously put out of sight: pronouncing peremptorily on the destinies of their miserable fellow-creatures, scattering broadcast sentences of death or slow torture, consolation under mitigating conditions, reprieves, or plenary absolution. Custom may lighten the weighty load of their responsibilities, but surely all the same it must sometimes sit heavily on them. For, after all, they are human like the patients, and occasionally they must themselves be out of condition and far from feeling up to the mark. Case after case and often for the first time, is brought panoramically beneath their observation, and each minute is precious when there are so many to be advised. They are invited at a moment's notice to diagnose the origin and the course of complicated and obscure diseases; they are asked in the way of ultimatum all manner of embarrassing questions as to methods of treatment and probable results. They must answer the main questions to the best of their ability, and if they do not actually put forward claims to infallibility they are bound professionally to speak with the assurance attaching to their position. As a rule they are sympathetic and strive to soften down unfavorable opinions, but there are desperate cases, and not a few of them, in which it would be cruel kindness to conceal the truth. The mother who brought a daughter she fancied was merely delicate, lifts herself in speechless anguish into the dismal four-wheeler in the conviction that her child is in a hopeless decline. How the sun has been darkened to her during the last long hour or two! and, like Scott standing over the grave of John Ballantyne, she feels it will never again shine on her so brightly as before. The husband who thought there was nothing serious the matter with his young wife reads solemn warnings in the ambiguous prognostications of the oracle, and, striving manfully to master his vague apprehensions, knows well that his wedded happiness is at an end."

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 10, 1889.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 10, 1889, TO AUGUST 16, 1889.

By direction of the Secretary of War, a Board of Medical Officers to consist of Lieutenant Colonel ANTHONY HEGER, surgeon; Captain JOHN O. SKINNER and Captain JAMES C. MORRILL, assistant surgeons, will assemble at the U. S. Military Academy, West Point, N. Y., on August 25, 1889, or soon thereafter as practicable, to examine into the physical qualifications of the candidates for admission to the academy. Par. 9, S. O. 185, A. G. O., August 12, 1889.

Leave of absence for one month is hereby granted Major William H. Gardner, surgeon U. S. Army, Washington Barracks. Par. 1, S. O. 183, Headquarters Division of the Atlantic. Governor's Island, New York City, August 13, 1889.

Major WASHINGTON MATTHEWS, surgeon in U. S. Army, promoted to surgeon U. S. Army, with rank of major, to take effect from the tenth day of July, 1889. Vice Town, promoted. War Department, Washington, D. C., August 14, 1889.

Leave of absence for one month, to take effect about October 1, 1889, with permission to apply to Division Headquarters for an extension of one month, is granted Captain VALERY HAVARD, Assistant Surgeon, U. S. Army. Par. 3, S. O. 86, Department of Dakota, St. Paul, August 10, 1889.

By direction of the Secretary of War, Captain JOSEPH Y. PORTER, assistant surgeon, now at Jacksonville, Florida, will, if the state of his health will permit, proceed to Jackson Barracks, Louisiana, and report to the commanding officer of that post for temporary duty, and by letter to the commanding general Division of the Atlantic. Par. 16, S. O. 186, A. G. O., August 13, 1889.

By direction of the Secretary of War, the leave of absence is granted Captain WM. C. GORGAS, assistant surgeon, in S. O. 84, July 3, 1889, Department of the Missouri, is extended two months. Par. 2, S. O. 182, A. G. O., Washington, August 8, 1889.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 17, 1889.

B. F. ROGERS, surgeon. Detached from U. S. S. "Alliance," and wait orders.

G. E. H. HARMON, surgeon. Ordered to the U. S. S. "Constellation." August 13th.

C. H. P. LOWNDES, assistant surgeon. Ordered to the U. S. S. "Constellation." August 13th.

C. J. DECKER, assistant surgeon. Detached from U. S. S. "Lancaster," and granted four months leave of absence.

L. B. BALDWIN, past assistant surgeon. Detached from U. S. S. "Ranger," ordered home and wait orders.

H. P. HARVEY, surgeon. Ordered to the U. S. S. "Ranger."

P. A. LOVERING, past assistant surgeon. Ordered to the receiving ship "Wabash," at Boston.

C. A. SIEGFRIED, surgeon. Ordered to the Naval Station at New London, Conn.

SOCIETY NOTICE.

FIFTH DISTRICT BRANCH NEW YORK STATE MEDICAL ASSOCIATION.— The Seventh Annual Meeting of the Fifth District Branch will be held in the Fowler House, Port Jervis, at 2 P. M., on Tuesday, August 27, 1889. Scientific Papers: Some Observations on the Use of Concentrated Lactic Acid, by W. B. Eager, M.D.; The Treatment of Typhoid Fever, with special reference to the Cold Water Method, by J. H. Hunt, M.D.; Presentation of a Case of Empyema, by H. B. Swartwout, M.D Presentation of Specimens. Voluntary Communications.

OBITUARY. JAMES L. CABELL, M.D.

DR. JAMES L. CABELL, senior member of the Faculty of the University of Virginia, died at Overton, Va., August 13th. He was born in Nelson County, Va., in August, 1813, and was graduated when twenty years old from the University of Virginia, and subsequently filled the chair of Anatomy and Surgery in that institution. He had charge of the Military Hospitals of the Confederacy during the Civil war, and he was Chairman of the National Sanitary Conference at Washington during the yellow fever epidemic at Memphis, and was later President of the National Board of Health. He was the author of "The Testimony of Modern Science to the Unity of Mankind."

OBITUARY. LE BARON RUSSELL, M.D., M.M.S.S.

Dr. LE BARON RUSSELL, a well-known resident of Boston, died at his summer residence in Plymouth, August 19th, after a long illness.

Dr. Russell was a native of Plymouth, and was born July 29, 1814. His father was Nathaniel Russell, who was largely engaged in iron manufacturing at that time. Entering Harvard College, he was graduated in 1832. He graduated from the Harvard Medical School in 1836, and became a member of the Massachusetts Medical Society in 1842. He studied medicine abroad, and for a time practised his profession in Otis Place, Boston, but having ample means, he devoted the greater part of his life to work of public utility, educational and otherwise. He never married. An early abolitionist, he was actively interested in making Kansas a free State. He was stanch in his support of the Union during the war, and was a warm friend of the negro race, doing much to aid the establishment of colored schools in the South. He was for many years a member of the Boston School Committee, showing particular interest in the normal school. He also gave much attention to the training-school for nurses. He served on the Board of Trustees of Harvard College for twelve years, and at the time of his death, was one of the Trustees of the State Lunatic Asylum at Taunton. Dr. Russell numbered among his friends Thomas Carlyle, whose work "Sartor Resartus," he was instrumental in introducing to an American public through an American publishing house.

OBITUARY. HERMAN B. INCHES, M.D. M.M.S.S.

DR HERMAN BRIMMER INCHES, a well-known resident of Boston, and the last occupant of a residence on Tremont St. — once the most attractive locality in Boston for private families — died August 19th, in the seventy-seventh year of his age. He came of a well-known Boston family, and was a member of the class of 1822, in the Boston Latin School, and was graduated from Harvard College in the distinguished class of 1831, which included his life-long neighbor, the late Dr. George Bethune, and many other well-known citizens. He received his degree of M.D., in the Harvard Medical School in 1834, and studied medicine with Dr. Warren.

A FEW CASES OF SPASM.

BY S. G. WEBBER, M.D.

THE great variety in the character of the convulsive action in cases of spasm is one of the interesting features of that morbid condition. The following cases seem of sufficient interest in this respect to report. I do not intend to explain their causes nor their nature, only to give the chief clinical features, which may find their counterpart in the practice of others.

The first case is one of those peculiar convulsive affections which has received the name of paramyoclonus multiplex. This case is of special interest because occurring in a woman, most of the patients having heretofore been men.

Dr. Allen Starr (*Journal of Nervous and Mental Diseases*, July, 1887), has given a very full *résumé* of all the cases he could find up to that date, and reported one of his own. Since then several other cases have been recorded. The latest paper which has come to hand at the time of writing this is one by Alessandro R. Marina, in the *Archiv. für Psychiatrie und Nervenkrankheiten*, XIX, p. 684. He gives a tabular view of twenty-two cases, of which two are his own. Two other authors have printed papers on the same subject, which had not appeared when he wrote his; namely, Theodor Ziehen (*Archiv. für Psychiatrie und Nervenkrankheiten* XIX, p. 465), and Eugen Kny (*Ibid*, p. 576).

Ziehen concludes that idiopathic myoclonie as well as the symptom of myoclonus are the expression of an increased irritability of the spinal centres. He gives several cases which are not well-marked cases of the paramyoclonus of Friedreich, but vary widely from the combination of symptoms as given by the latter. It seems to me that the first and second cases which I report may be brought into such a relation as Ziehen suggests, but the other of my cases cannot be thus related to each other. I report them only as interesting cases of spasm, without the intention of referring them to any common class.

Miss M. I., age twenty-eight, entered the Adams Nervine Asylum in July, 1887. She had measles when young, and had never been well since. She had violent headaches and nausea at the catamenial period, also backache and inguinal pain, but the head trouble is what she complained of most. She was said to have had an attack of congestion of the lungs the winter before her entrance, but judging by her condition while she was having such an attack, it is probable that the congestion was merely a sense of tightness and constriction due to purely nervous causes. At times she was said to get so confused that she found it hard to collect her thoughts to answer questions.

Dr. Clark, who sent her here, stated that she had anteflexion and a prolapsed ovary, but did not think the head trouble was dependent upon these as cause; the abdominal symptoms seemed to amount to very little.

The patient stated that she had been in bed twelve years, with tired feeling in head, headache, backache, aching in the arms and legs, and pain after eating. There was no tremor of the hands; co-ordination of the hands was good; there was only slight patellar tendon reflex; the plantar reflex was well-marked on both sides. She complained of feeling sore and tender all over; on examination there was found some tenderness to touch and pressure over the abdomen, stomach, between the scapulæ, and at the junction of the lumbar and sacral vertebra. Her feet were cold and slightly œdematous. The pulse was 84. Tongue was large and flabby, rather pale. She showed herself during the examination to be quite hysterical; at very slight causes she jumped with convulsive twitches of the arms and shoulders.

The urine was of a high color, specific gravity 1,036. It was very acid, no albumen, no sugar, sediment normal.

She had many of the convulsive twitchings above referred to, complained much of headache, and showed herself very hysterical. As little notice of her complaints was taken as possible. She was urged to get up, was sent to ride, was kept out doors as much as the weather would permit and her strength would allow. The chief means of treatment used were quieting remedies, as the valerianates, gelseminum, small doses of bromides, salt baths, dry cups to the spine.

She did not improve; the spasmodic action increased in severity, and was more frequently and easily excited. After about three months the legs were affected as well as the arms; there was pain in the toes; she was nervous and restless, and cried out in her sleep.

After about four months an examination showed that the plantar and knee-jerk reflexes were stronger on the right, though neither patellar reflex was very strong. The spasms which occurred, on entrance, at rare and irregular intervals, had become quite frequent, but still recurred at very irregular intervals. They were clonic in character, at a rate of about one hundred and fifty or more in a minute, the attacks coming sometimes near together and again being absent during many hours. The legs were more frequently affected than the arms; the thigh muscles were those most convulsed. The muscles of the face were sometimes affected, especially those about the mouth and orbicular muscles of the eyes, and to a less degree those of the forehead. At times, when standing, the spasms attacked the muscles of the back, obliging her to take several short steps backwards to avoid falling. Noises had no influence in producing the attacks; but the entrance of a stranger, or any emotional excitement, increased their frequency and severity. A gentle tap on the leg would also bring on an attack, more surely of the right leg. She complained of considerable discomfort in her head. She did not walk in a straight line, but rather to one side.

On using the galvanic current to the back, from the fifth cervical to the lumbar vertebræ, the muscles of the head and face seemed to move more than previously. When the sponges were placed on the tenth dorsal and the lumbar vertebræ, the head and face were not affected, and rarely moved. The spasms of the legs were increased during the galvanization. No spasms occurred while the patient was talking.

The spasmodic phenomena were not diminished by treatment, but rather increased in severity without regard to what was done. When the patient left, the attacks were about the same as they were several weeks previously. In many cases of paramyoclonus electricity has been of value in relieving the attacks, but in this case it had no beneficial effect.

Mrs. M. E. E., age thirty-five, entered in 1887, suffering with nervous spasms. Her mother had ner-

vous prostration, her father was consumptive. She had been sick about two years; at first tired, coughing, restless, and unable to keep still. She was put to bed, and improved. There were dyspeptic symptoms, and at times an effort to raise gas, which seemed to depend upon a spasm of the diaphragm. There was also a peculiar jerking of the arms and head. After six months she was put to bed again, was fed, and in three months gained eight or ten pounds. She was better as to the jerking and jumping. She was up and about during the summer, and gained until winter; then she began to have the spasms again. These spasms consisted in a jump, when there was any noise, especially if it was sharp or unexpected. When such a noise was heard, she would rise from a recumbent posture to sitting, with a sudden start, with a clasping of the hands and a twitching of some of the muscles of the face, giving her a look of terror as if frightened. Sometimes the start was not sufficient to raise her body, but she would then seize her hands and clasp them tightly, or she would put out her hand and catch hold of the hand or clothing of any one sitting by the side of her bed; then, in addition to seizing hold of the object, she would pull strongly, and twitch and jerk the object she had taken hold of. Even very slight sounds would cause at least a slight contraction of the muscles, and a start as if she were about to have a stronger spasm. The noises which were most likely to give rise to these phenomena were of a sharp character, on a high note; those lower in the scale had a very much less effect. An unexpected noise would produce a more violent spasm than one which was anticipated. In talking with her, it was necessary to speak in a low tone, or choose those words for the first in a sentence which did not begin with an explosive sound. It mattered not whether the noise was in the room or out-doors, the spasm occurred the same, though less severe when distance made the sound fainter.

She had been married eleven years; nine years ago had miscarried at the fourth month. Menstruation was regular. The summer previous the pupils were much dilated; they were so when she was first seen. They reacted normally. There was no headache; patellar tendon reflex was strong; there were no symptoms indicating any special lesion of brain or cord. She was often very tired from the frequent jumping and jerking.

I was told by her physician that an examination had showed no uterine disorder.

Various means were employed to relieve the spasms, but apparently to no purpose. Different internal remedies, — ether-spray to the back, the actual cautery, dry cups, electricity, — all proved ineffectual. Sometimes the irregular action of the muscles was less than at other times; but there seemed to be no connection between any improvement and any remedy.

Miss A. L. P., age twenty-eight, entered the asylum in January, 1888. She was a very tall and unusually large woman. Notwithstanding her size, there was an appearance of lack of endurance, and less real physical and nervous strength than would correspond with her size. She was a nurse by profession, and had had a rather hard time nursing relatives.

The patient said she had had severe attacks of headache for three years, during which the whole head "felt as if frozen." These attacks occurred once in two or three months. There was also pain from the top of the head down the spine. These paroxysms of pain were described by her doctor as being very severe and quite beyond her endurance and control, and inducing hysterical manifestations. These attacks recurred frequently through a period of many weeks.

Her attending physician found a marked erosion about the os uteri, with a mucous discharge from the os. This condition was corrected, and she was in many ways better, but the pain in the head and spine was still sufficient to incapacitate her from work.

She had a slight degree of astigmatism, which was only partially corrected. The glasses enabled her to see pretty well.

On examination, it was found that there was some tenderness in the cervical, middle and lower dorsal regions of the back; the abdomen was not tender; there was a slight amount of tympanites over the stomach; and she complained of occasional distress from flatulence. The pupils reacted normally; the tongue was pale and flabby; pulse was not very strong, seventy-eight. The first sound of the heart was accompanied by a rough murmur; loudest over the aorta, and this sound was transmitted to the apex; the second sound was somewhat accentuated.

For about a month the patient did very well, having no very severe attack of distress, and the headache being relieved by the application of cold and heat alternately to the back of the neck, and by the use of aconitia internally. She seemed in a fair way of speedily recovering. At the end of a month there was a slight disturbance in the ward, on account of the examination of another patient. After this she was not so comfortable, had more trouble with her head, and showed more evidence of hysterical tendencies. A week later she had a severe attack of pain in the back of her neck, with a spasm of the muscles drawing the head backwards in tonic contraction; this was so strong that the nurse was unable to keep her on the bed, and she rolled off onto the floor. When I saw her the spasm was less violent, though still quite strong; the body and neck were bent back in a state of opisthotonos. The contraction was intermittent, continuing for a minute or two, then relaxing for a short time and recurring again. I bent her head forwards during one of the spasms, bringing it into the ...ad, and for... position, when the spasm ceased. I then forci... his life kept the head from returning to the unnatural position, and there were no more spasms.

After this attack there was severe headache for several days, and a tendency to retraction of the head; but hypodermic doses of atropia, or of atropia and morphia, were sufficient to prevent an attack until about ten days later, when she had another severe one, which was relieved in less than fifteen minutes by the application of the galvanic current to the neck. The application of galvanism to the neck every other day served to relieve the pain, and there was no attack for nearly two months, and only occasional headache. During this time she gained in general health and strength. After this period of comparative freedom she had, for ten days, more pain in the back of the neck and slight spasms, but not severe enough to attract special attention at the time, and they were easily relieved. Then there recurred at short intervals two very severe attacks of spasms. In the second of these she was under the observation of my assistant throughout the whole attack. The attack began with pain in the back of the neck, which increased rapidly in

severity; then the limbs trembled, there was clonic spasm for a few seconds, affecting chiefly the arms, they being rigid in extension and pronation, with the wrists slightly flexed. This was followed by tonic contraction of the muscles of the back and neck, the arms being also rigid and extended. There was opisthotonos; this lasted for several minutes. There was no loss of consciousness. Towards the close of the spasm there was a change in the expression of the face, which it was not easy to describe, a sort of far-away look in the eyes, a vacant expression. She said that her tongue felt as if it was drawn back into the pharynx.

This whole attack had a very strong resemblance to an attack of hystero-epilepsy. The first and second stages were quite well marked. There was only a slight suggestion of the third period, that of hallucinations, in the change of expression towards the close of the attack.

The day after the attack an examination showed an unnatural tenderness over the left ovary, but there was no recurrence of spasm on pressing over that organ.

A few days after the above scene I took an opportunity, when she was quiet and free from pain, to tell her that the attacks were hysterical and to some extent under her control; that there was no organic disease; and that she must try to control herself. I suggested that, when she felt the spasm coming on, she should rise and walk about her room, and thus throw off the influence, and perhaps avoid having an attack. The statement that there was no organic disease seemed to relieve the patient's mind to such an extent that she had no more severe attacks, and only once did she find it necessary to try to walk off the tendency to an attack. She remained under observation a month or more, and has been heard from several times since, and has been fairly well. I have not heard of her having any serious disturbance.

In this very interesting and peculiar case there are several circumstances that attract attention. Was this a case of true hystero-epilepsy? Two stages or periods of that affection were clearly represented in the spasm. The first stage, that of the epileptoid attack, was of short duration; then followed a series of clonic convulsions, resembling those of epilepsy. This was also of short duration, and was succeeded by a period of great movement, in which the opisthotonos was the position assumed. It is doubtful if there was anything to correspond with the third and fourth periods of Richer. Pressure over the ovaries was not tried during the attacks, but afterwards, on the next day, it had no special effect.

In view of the whole history of the patient, I think it is more probable that the convulsions were not hystero-epileptic, but were simply hysterical, and had a strong resemblance to the more serious affection. Whether the patient had ever heard of or seen a case of hystero-epilepsy, I do not know. As she was a nurse, it is possible that she may have, and that unconsciously, or without any design, the attacks may have taken the form they did by a species of involuntary imitation.

The good effect of an explanation of the spasms to the patient could hardly be expected in every case of hysteria; but perhaps would follow in more cases than one at first would expect.

The following case is of interest as belonging to that class of neuroses which are dependent upon uterine disturbances of a more or less functional nature.

Miss M., age twenty. Menstruated first at about the age of fourteen, but the function was not fully established, the flow recurring only once or twice a year for the first four years or so, then at more frequent but irregular intervals. The flow was scanty at first, later it was more natural.

She is a well-nourished young lady, of good flesh, good color, no appearance of anæmia, seemingly strong and robust. She has a good appetite, can walk without excessive fatigue, in fact, does walk a mile or more twice a day. She has no recollection of a fright or any shock which might have acted as an exciting cause of the peculiar spasms on account of which she sought advice. She has attended and taught school continuously during most of her life, and there seemed to be nothing in her occupation to give rise to the spasms.

At about the time her catamenia first appeared, five or six years ago, she began to have starts or twitches. The first of these attacks occurred while she was asleep on a lounge. She awoke with a start, with no consciousness that she had been dreaming, no knowledge that a noise or any external cause had aroused her. It was just after this that the spasms began. There is a sensation of a contraction in the throat, as if she were clutched by some one, rather like the globus hystericus, as she described it. This sensation passes downward to the stomach and bowels, upward to the mouth. The twitching seems to be internal, yet it is sometimes visible in the lower part of the face; the muscles of the upper part of the face are not affected. The attacks occur towards night, especially when she is tired, sometimes in the morning. Sometimes she goes to bed and to sleep, then will jump and spring out of bed; at times the spasms will continue for three or four hours. She often twitches just before dropping to sleep. When the attacks are very bad, they interfere with breathing, the face becomes flushed, she is exhausted by the severity of the spasms, and then needs to go to bed earlier, and can sleep sooner. After falling to sleep she often sleeps well, but there may be twitching without waking, as shown by the action of the muscles. During her visit she sighed frequently, and the respiration was in that respect irregular. For the last two or three months there has been a sense of pressure in the head, and sometimes pain through the head.

These attacks are more frequent and severe at the time when the catamenia ought to appear, if they are absent or delayed. When the periods are more regular the attacks are less, or may be absent. When in company, or interested in her work, or in conversation, the twitching does not occur. Consequently, there was none of it during the visit. There were no objective symptoms.

A uterine examination had been made before I saw her; and I was told that the physician had found an undeveloped uterus, for which electricity had been used, and since then the catamenia had been more regular.

The next case is one of those singular hereditary neuroses, which are occasionally found to prevail in certain families, and are different from similar cases outside these families. These may be designated as "family" neuroses; and, in that they recur so frequently in the one family and are not met outside that family, they differ from the ordinary hereditary neu-

vous prostration, her father was consumptive. She had been sick about two years; at first tired, coughing, restless, and unable to keep still. She was put to bed, and improved. There were dyspeptic symptoms, and at times an effort to raise gas, which seemed to depend upon a spasm of the diaphragm. There was also a peculiar jerking of the arms and head. After six months she was put to bed again, was fed, and in three months gained eight or ten pounds. She was better as to the jerking and jumping. She was up and about during the summer, and gained until winter; then she began to have the spasms again. These spasms consisted in a jump, when there was any noise, especially if it was sharp or unexpected. When such a noise was heard, she would rise from a recumbent posture to sitting, with a sudden start, with a clasping of the hands and a twitching of some of the muscles of the face, giving her a look of terror as if frightened. Sometimes the start was not sufficient to raise her body, but she would then seize her hands and clasp them tightly, or she would put out her hand and catch hold of the hand or clothing of any one sitting by the side of her bed; then, in addition to seizing hold of the object, she would pull strongly, and twitch and jerk the object she had taken hold of. Even very slight sounds would cause at least a slight contraction of the muscles, and a start as if she were about to have a stronger spasm. The noises which were most likely to give rise to these phenomena were of a sharp character, on a high note; those lower in the scale had a very much less effect. An unexpected noise would produce a more violent spasm than one which was anticipated. In talking with her, it was necessary to speak in a low tone, or choose those words for the first in a sentence which did not begin with an explosive sound. It mattered not whether the noise was in the room or out-doors, the spasm occurred the same, though less severe when distance made the sound fainter.

The twitching seems to be internal, yet it is sometimes visible in the lower part of the face; the muscles of the upper part of the face are not affected. The attacks occur towards night, especially when she is tired, sometimes in the morning. Sometimes she goes to bed and to sleep, then will jump and spring out of bed; at times the spasms will continue for three or four hours. She often twitches just before dropping to sleep. When the attacks are very bad, they interfere with breathing, the face becomes flushed, she is exhausted by the severity of the spasms, and then needs to go to bed earlier, and can sleep sooner. After falling to sleep she often sleeps well, but there may be twitching without waking, as shown by the action of the muscles. During her visit she sighed frequently, and the respiration was in that respect irregular. For the last two or three months there has been a sense of pressure in the head, and sometimes pain through the head.

These attacks are more frequent and severe at the time when the catamenia ought to appear, if they are absent or delayed. When the periods are more regular the attacks are less, or may be absent. When in company, or interested in her work, or in conversation, the twitching does not occur. Consequently, there was none of it during the visit. There were no objective symptoms.

A uterine examination had been made before I saw her; and I was told that the physician had found an undeveloped uterus, for which electricity had been used, and since then the catamenia had been more regular.

The next case is one of those singular hereditary neuroses, which are occasionally found to prevail in certain families, and are different from similar cases outside these families. These may be designated as "family" neuroses; and, in that they recur so frequently in the one family and are not met outside that family, they differ from the ordinary hereditary neu-

roses. It may well be doubted whether the patient's explanation of the origin of the complaint is the true scientific explanation. I give it as he told it. The symptoms suggest Thomsen's disease, yet differ from that in several particulars. It cannot be classed as tetany, as it does not agree with that combination in all respects.

J. R. was seen early in 1885. He was then about twenty-four years old. The family history is interesting. The patient's maternal great-grandfather, after violent exercise while hunting, felt something give way in his back. His son, the patient's grandfather was born with a similar trouble in his back. The patient's mother had the same trouble, but not until about the age of sixteen. The mother had one sister, who died at twenty-five years, free from the affection; two other sisters were affected. One of these sisters had no children. The other sister had two boys, not affected (one died at twenty-five, the other is living at thirty-five); and one girl, who was affected.

The patient has two brothers and three sisters; the two brothers, younger, are affected; one sister, older, is affected; two younger sisters, one sixteen the other nearly eighteen, are not affected. One sister died at seven, not affected. Some of these relatives are troubled more than others, but otherwise the symptoms are the same in all; none are totally disabled. His sister has had no attack for a year, but she takes less exercise.

The patient was well until he was sixteen years old, except he had had a "slow fever" annually, in winter, for two or three years, which kept him in the house for a week or ten days. His face flushes readily, the vessels dilating slowly, and remaining so for an hour or more.

He was born in October. The November or December after he was sixteen he skated until he was tired. The next morning he had trouble in the calves of both legs; felt stiff all over. This passed off readily. Subsequently, violent exercise brought this on again; and each time it passed off less readily, or as he expressed himself, "It was harder to work it off." This stiffness was not like cramp. There was no pain; it was a numb, stiff feeling in his back, noticed most after being still and then trying to move, and was worse after sitting down then after lying down. Violent excitement, or a fright, would cause the spasm, not at once, but after fifteen minutes.

These attacks are not now any more readily produced, but they are more severe than at first. If the attacks have been frequent, violent exercise will cause one during continuance of the activity. When he has been long exempt, the attack is postponed. Sometimes he is free three months continuously, then the stiffness will "hang around him" for a week at a time.

The attacks are sometimes delayed for thirty hours after the cause has operated. Usually they occur about two or three o'clock in the night, rarely at midnight. They awaken him, and usually pass off by nine o'clock in the morning. He thinks he is awakened because he cannot move his limbs. The attacks do not begin after rising, but if slight on rising, may increase in severity, so that occasionally, after leaving home, he has been obliged to return, it being impossible for him to continue with his daily duties.

In the severest attacks, of which he has had three in two years, he cannot move his limbs nor turn in bed; he cannot move a finger; he can move his lips and talk and smile; cannot open his jaws wide; cannot gape nor cough. These severe attacks last longer than formerly, sometimes forty-eight hours.

In the lighter attacks, after sitting, he has to rise slowly, stand straight, and throw his body backwards, or he falls; then it is difficult to raise his leg, and it drops, or "throws itself down." By resting a moment, he walks better. His hands are also stiff. There is some trouble in articulating.

During the attack there is no disturbance of sensation, no pain, no headache, no vertigo, except in very severe attacks. The pulse is slow; the body seems hot; there is no perspiration; and never unconsciousness. The sight may be blurred for a while. If he is at work, his face flushes.

The patient was a well-built, healthy-looking man. At the visit, his face was red. The amount of color varied during the visit. The pupils were large. When uncovered, they contracted slightly, then dilated. When examined for accommodation, with the light falling on the eyes, they did the same; but when turned from the light, the reaction for accommodation was normal. The conjunctiva was rather congested. The motion of the eyes, tongue, face and hands, was natural at the time of visit. Sensation was normal. He walked naturally. There was no inco-ordination of legs nor hands. Patellar tendon reflex was slight, and equal on the two sides. The ophthalmoscope simply showed that the small vessels were very distended.

THE SOMERVILLE CASES OF ARSENICAL POISONING.[1]

BY T. M. DURELL, M.D.

On the fourth day of August, 1886, William J. Robinson, a strong young man of twenty-two years, was struck on the back of the neck by an empty soap box falling upon him. He went home and told his mother of this injury; she prepared his dinner, which he ate; and almost immediately he complained of pain in his head, and began to vomit. He returned to his work, but vomited several times during the afternoon, and complained of headache. The next day he was much worse; he had severe frontal headache and sighing respiration; his face was flushed, his eyes injected; pulse 90; temperature, 100°. The heart's action was weak. This condition of things was found by Dr. E. L. White on his first visit. The story of the accident was told, but this did not seem to be enough to account for the condition of the patient.

August 6th. The headache was less severe and the vomiting less frequent. There was a slight papular eruption over the surface of the body.

August 7th, 7.30 P. M. Vomiting constantly, excessive thirst, burning pain in the throat and stomach, and severe diarrhœa; the headache had disappeared; the face was red, and the eyes injected. The mind was clear.

August 8th. The above symptoms continued during the day, with more eruption.

August 9th. The face was flushed; the eyes were injected and jaundiced; the respiration was sighing; the temperature was 100° and the pulse 104. There was burning pain in the fauces and stomach, with

[1] Read before the Massachusetts Medico-Legal Society, February 6, 1889.

great thirst; the liver and spleen were enlarged. Up to this time, no vomitus or urine could be obtained, as they were thrown away immediately; but during the visit the patient vomited, and the vomitus was taken by the physician, and sent to Dr. Wood for analysis. Crystals of white arsenic were found. In the afternoon there was some vomiting, and the diarrhœa continued; but the patient was rather more comfortable. Mrs. Robinson was very anxious to know what had been done with the vomitus.

August 10th, 9 A. M. Patient better. Temperature, normal; pulse, 100, rather weak; respiration, 24, sighing, but not as much so as before; less diarrhœa and vomiting. At 8.30 P. M. the pulse was 112, weak. Severe nosebleed during the day, and great pain in the throat.

August 11th. Much worse; liver and spleen more enlarged; pulse 120, and weak. There were many patches of ulceration in the mouth, insides of the lips and throat; throat very red; body jaundiced; eyes bloodshot and jaundiced. There was a papular eczema over the surface of the body and limbs. The abdomen was swollen. The mind was wandering at times. The patient was very restless. At 5 P. M., pulse, 134; and respiration, 36; no second sound of heart; the skin was cold and clammy.[2]

The patient died early in the morning of the 12th, and I at once took charge of the body and had it removed; and at 1 P. M., (nine hours after the death), I made an autopsy, in the presence of Drs. A. F. Holt and J. L. Hildreth, as witnesses, and found the following appearances:

Rigor mortis was fairly well marked. The pupils were moderately dilated. The dependent parts of the body were of a dark bluish color; other parts of the body and limbs were covered with blueish spots, irregular in outline, varying in size from half an inch to several inches in diameter. Scattered over the body were some blackish spots, varying in size from a pin's head to that of a pea (ecchymoses). Careful inspection revealed no external marks or signs of violence. The inside of the mouth and the tongue were covered with deep ulcerations. On making the cut to open the great cavities, the muscles were seen to be of a bright red color, and those of the chest were well developed. There was about six ounces of straw-colored fluid in the abdominal cavity; the peritoneum was everywhere clear and glistening; the intestines were distended with gas.

The liver was enormously enlarged, nearly filling the abdominal cavity, and was of a bright yellow color.

There were about eight ounces of dark, bloody fluid in the left pleural cavity; a little less, of a lighter color, in the right.

Both lungs were adherent at the top and back. In other parts, the pleuræ were clear and glistening.

There was about two ounces of straw-colored fluid in the pericardial sac. The pericardium was clear and glistening on its inner surface. The heart was about the size of the right fist. A small quantity of dark fluid blood flowed from the cut vessels in removing the organ. There was a little fluid blood in the right side of the heart, and a very small well-organized clot. The auriculo-ventricular opening admitted three fingers. The left side of the heart was empty. The auriculo-ventricular opening of this side admitted two fingers. All of the valves of the organ were normal in appearance, its cavities of normal size, and its walls were of normal thickness. The muscular fibre of the organ was of a red color, and slightly soft.

The left lung was generally of a dark red color; the vessels were full of blood; the bronchi were filled with frothy mucus; a quantity of dark bloody fluid could be squeezed from the cut surface. The right lung was generally in the same condition as the left, with the exception that it was of a lighter color in the upper portions. The trachea contained a quantity of frothy mucus. The œosphagus was normal.

The spleen was enlarged to twice its normal size, and was of a bluish color; on section nothing abnormal was found. The left kidney was a little enlarged, of a uniform bluish color; its capsule was adherent, tearing the tissues on its removal. Section showed the blood-vessels to be moderately full of fluid blood; the cortical portion was of a reddish-gray color, normal in thickness; the tubular portion was of a bluish color, and the vessels in it could be seen as red lines. The right kidney was slightly larger than the left, and like it, with the exception that the cortical portion was of a grayish-yellow color, and the vessels could be seen in it as well as in the tubular portion. The ureters and bladder were normal; the latter contained about four ounces of urine.

The large intestines were distended with gas, and contained a yellowish-green material, as well as some small semi-solid portions of fæcal matter. There were a few spots, especially in the lower part, that were red, and the vessels were injected about these. The spots were about the size a five-cent piece.

The small intestines contained a quantity of yellow, gelatinous material; the mucous membrane was red in spots. The mucous membrane of the duodenum was of a red color and the rugæ were almost black.

The stomach was dilated to the capacity of a quart, and contained about half a pint of dirty, greenish liquid. Its external coat was of a grayish color except in the dependent parts, where it was red. The mucous membrane was red in patches, and scattered over a greater part of it were a large number of small ecchymoses. The vessels were injected.

The liver was of a striking yellow color, reddened in spots and greatly enlarged. The cut surface was of the same yellow color, and the acini could not be made out. The vessels were partly filled with fluid blood. The gall-bladder was filled with a reddish watery pile; its duct was free. The pancreas was normal in appearance.

No blood flowed from the cut vessels of the scalp. The skull was normal in thickness and appearance. The dura mater was of normal thickness, translucent and glistening on its inner surface. The pia was everywhere clear and glistening, its vessels were moderately full of fluid blood, particularly on the left side; those of the base were empty. Careful section of the brain and great ganglia showed them to be everywhere normal in appearance.

The organs were carefully sealed and delivered to Prof. E. S. Wood and Dr. Charles Harrington for analysis. Both of the chemists found large amounts of arsenic in the organs delivered.

This case was one of a series of cases of poisoning by the use of arsenic, — a series unequalled, I believe, in the history of crime. There are many cases on record where a woman has poisoned several persons,

[2] For the above history, I am indebted to the kindness of Dr. E. L. White, as I did not see the patient till August 11th.

either from hatred or for some other motive; but for a mother to poison her own children is, I believe, without parallel.

Mrs. Robinson's career in arsenical poisoning began in Chelsea, thirteen years ago. At that time, Joseph Field, who married Mr. Robinson's sister, became attached to Mrs. Robinson and left his family and went to board with her. He had a large amount of money and government bonds, which he kept in a box in his room. Shortly after he went to board with Mrs. Robinson he was taken sick with symptoms of poisoning, and died. After his death no trace of the money or bonds was ever found; but Mrs. Robinson went to Dr. Bean, who attended Field, and asked him how she could get money for a government bond which she had. At that time the doctor thought that Mr. Robinson had poisoned Field from jealousy.

Later, the Robinson family went to live in a house owned and occupied by Oliver Sleeper and his wife. While there Mrs. Sleeper died, and Oliver took his meals with the Robinsons. Sleeper received something over $10,000 in money, and carried it home with him; and directly after this he was taken sick and died. His sickness was due to slow poisoning; and arsenic was found in his remains when exhumed. When the administrator took charge of his effects the money was gone. Mrs. Robinson nursed him during his sickness. Sleeper died August 10, 1881.

July 23, 1882, Moses Robinson (Mrs. Robinson's husband) died, after an illness of six days. The prominent symptoms were vomiting and diarrhœa. Shortly before this, Robinson made application for insurance to the New England Relief Association for $2,000 which was made payable to his wife. Just before his sickness Mrs. Robinson went and asked if his insurance papers were all right. She brought suit to recover the insurance but failed to recover for some technicality. Arsenic was found in his body.

The Freeman family consisted of four persons, Mr. and Mrs. Freeman and two children. Mrs. Freeman was a sister of Mrs. Robinson. Prince Arthur Freeman had his life insured in favor of his wife, and this wife, Annie E. Freeman, was taken sick with symptoms of poisoning, and died February 26, 1885. Mrs. Robinson nursed her during her sickness. Arsenic was found in her body.

The baby, Elizabeth Bell, died April 16, 1885, Mrs. Robinson being her nurse. No arsenic was found in this case, although the baby was nursing at the time of the mother's sickness.

After the death of Mrs. Freeman, Mrs. Robinson persuaded Freeman to come and live with her; and the insurance policy was made payable to her, the idea being that, should anything happen to Freeman, Mrs. Robinson might have money to bring up the boy. Freeman died June 27, 1885, after an illness of six days, the symptoms were those of poisoning, and arsenic was found in his body.

Lizzie A. Robinson, a daughter of Sarah Jane, died at Somerville on February 22, 1886, after an illness of four weeks and five days. This illness commenced with an attack of acute rheumatism; but, during the course of the disease, she developed symptoms of acute Bright's disease. She also had severe vomiting and diarrhœa, and finally died, according to the death certificate, of acute Bright's disease. The physician who attended her made every effort to secure an autopsy, but her mother would not allow it. She was insured for $2,000. Arsenic was found in her body.

Thomas A. Freeman (son of Prince A.), living at Mrs. Robinson's, died July 23, 1886, after a very obscure illness. Arsenic was found in his remains. The motive in this case was to get rid of the boy, so that she might use the whole insurance money of the father.

Next came the case of William J. Robinson, who died August 12, 1886. He was insured for $2,000 in favor of his mother.

There was the same method employed in all these cases; the plan being to call in some physician for a comparatively slight sickness, and then administer the arsenic. In all of the cases physicians of good standing were called, and before they realized what had happened, the patient was dead. The result was, that, in a few years, nine persons died under the care of Mrs. Robinson; and in all of the cases except Field and the baby, arsenic was found in large quantities after death. In all of these cases the physicians who attended the various patients have made statements of the symptoms of their patients, and all of these statements correspond with the history of arsenical poisoning. One of the most remarkable things about these cases is the skill which was used by Mrs. Robinson in administering the poison; and this very skill would lead one to think that some one familiar with the properties and uses of arsenic must have been associated with her.

Mrs. Robinson was tried for the murder of her son, William J. Robinson, but the jury failed to agree on a verdict. Subsequently she was tried and convicted for the murder of her sister and family.

A CASE OF FRACTURE OF THE THIGH, WITH NON-UNION.

BY THOMAS H. MANLEY, M.D.,
Surgeon to Harlem Hospital, New York.

IN the early part of January, a lame man came into the Harlem Hospital, seeking relief to the distraint of an injured limb, and giving the following history:

He said that nearly two years (twenty-two months) before, while pursuing his usual occupation of lumberman, he got caught between two logs, and fractured his left thigh. He was brought to one of our largest hospitals for treatment. On entering, he was examined, and told that the bone was broken near the joint. A Buck's extension, with weights, was applied, and he was kept quiet for two weeks, when more extension was made, and plaster of Paris put on. In this the limb remained eight weeks. After removal, it was found that there was no union. Then he was etherized, and the ends of the bones rubbed together, and again the plaster was adopted as a splint.

At the end of three months this was cut down, but still no union. At this time a council of surgeons was held; and it was decided that there was probably something between the ends of the bone, which should be removed, and that while removing any impediment to union, they would wire. Again he was anæsthetized, an operation performed, and another layer of the powdered lime applied.

He said, that after this he suffered great pain for a long time, and had a profuse and long-continued discharge from where the wound was made. In the mean time, his weight had been reduced from one

hundred and seventy to one hundred and ten pounds. After the wiring of the femoral shaft, he was kept in the hospital thirteen months, most of the time in bed. He was then discharged, and was informed that the bone was united, and that, with use and friction of the limb, it would in time become supple and strong. He remained at home six months, and found no improvement whatever. On the contrary, pain was constant at the seat of the incision; and now, too, he discovered that the scar commenced to ulcerate.

Condition on entering Harlem Hospital. — He came in on crutches, and though more than two years had elapsed since the accident, he found himself, even now, unable to put any weight on the foot of the injured side. His general health seemed fair. On examination of the affected limb, it was seen that the knee-joint was motionless unless considerable force was used, when he would complain of its giving him some pain, more particularly in the region of the injury.

It was evident that the knee was not anchylosed (not as we understand it) from arthritic lesion, but was immovable through being firmly held by the unyielding hamstrings, vasti, and femoral rectus. The leg below was wasted and feeble; and, above, those once heavy, powerful muscles of the thigh, when compared with their fellows, were seen to be greatly shrunken and atrophied, from constant, continued pressure, and non-use. On the front aspect of the thigh, just anterior to the lesser trochanter, there was a long linear cicatrix, but broken in the centre, through which a thin, serous discharge exuded. Though there was some motion in the hip-joint, it was, nevertheless, very limited, and was attended with some pain when made with any degree of freedom,

The question was, What could we do towards improving our man's condition, and relieving him of his infirmity? It seemed to me that we could do very little. He was at the meridian of life, — forty-five years old, — and was altogether a different subject to operate on than a youth with active recuperative processes. He was especially anxious to get the use of his knee; but this we could not promise him, as it was evident that in the reparative processes about the seat of the wound lymph was thrown out in every direction, between and among all those large muscle-sheaths of the upper part of the thigh, extending from the bone to the skin, and, becoming organized, had formed a tough, leathery bond, sealing and soldering together everything promiscuously, — bone, tendon, vessels and muscles, — and preventing forever that free, sliding, easy motion of one muscle-sheath over the other, and hence the normal potency of the joint below.

We could do one thing, however; we could follow the fistulous opening, and remove, perhaps, the cause of it. But why, with good union, he could walk only with crutches, seemed a mystery. We examined the thigh, we thought, very thoroughly on his entrance, and felt assured of the solid continuity of the femur. The measure of relief we offered was very inconsiderable, yet he quickly consented to our efforts in the way of doing everything which might, in any degree, relieve him.

I commenced the operation by making an incision, in the same direction as the original, on the anterior aspect of the thigh, but about half an inch to its outer side, in other words, to the outer border of the sartorius and inner of the tensor-vaginal femoris muscles, directly over and through the rectus femoris, till the periosteum was reached. We found the tissues indurated, and inseparably matted together. The traces of former suppuration and extensive connective-tissue formation were well marked.

In following along the tortuous course of the fistula, we came to a small, angular piece of necrosed bone, which had, no doubt, been reduced in size from the solvent action of the discharge which its presence was the cause of. After removing this small, foreign substance, we cautiously groped further, avoiding the large nerve trunks and vessels which lie convenient to the femur in this situation.

Shortly we reached the bone, when, to our amazement, we found no osseous union whatever; but, owing to the false joint being so firmly embraced by the large muscles which run in the same direction as the shaft, and the large amount of new tissue formation, we were, as well as the surgeons in the hospital which he originally entered, deluded into believing there was true union. I would have readily sworn, that, to the best of my knowledge and belief, there was osseous connection of the shaft.

The wire used in holding the broken ends could be seen, blackened, but deeply lodged, on the under surface of the limb; and considerable dissection was necessary to reach it.

I did not wish to take the chance of deep suppuration, which might entail the loss of his limb or even life, and was contented with approximating the edges of the incision, and draining from below, with horse-hair. The wound healed up in a few weeks, when the pain ceased. Not being able to safely do anything further for him, he was dismissed.

This case, it would seem, is well worthy of recording, especially just now, when, owing to the presumed impunity with which tissues may be indiscriminately explored or opened, with antiseptics, considerable wiring of bone is being done. The case illustrates what has *always* been my experience, namely, that, for some reason not yet well understood, wiring shafts of bones does badly, no matter what care is taken. On the other hand, it is not unattended with danger; for, do what we will, pus will almost invariably form and infiltrate. The only exception is in children; where there is much displacement and shattering, the wire does not seem to cause the irritation it does in adults. It is the ideal treatment, *if practicable*, as the bones can be at once accurately apposed and held together, but the ends of them will either necrose, or the wire cause so much harm and inconvenience as to require removal.

I think, then, that it may be set down, almost as an axiom, that, in the adult, wiring of a bone is never justifiable, except when there is a compound fracture with shattering, or great displacement. Under any other circumstances, though its application seems simple, it is a dangerous and useless experiment.

— Dr. R. Jamin reports (*Abeille Médicale*, May 13, 1889) favorable results from the electrical treatment (eleven applications) in a case of nocturnal incontinence of urine in a young girl of fifteen, who had wet her bed nightly for years, and in whom he and others had obtained no amelioration by prolonged medicinal treatment. He used direct faradization with an olive-tipped bougie applied to the urethra, after the advice of Guyon. — *New York Medical Journal.*

Clinical Department.

A CASE OF LIGATURE OF THE INTERNAL JUGULAR VEIN: RECOVERY.[1]

BY E. H. BRADFORD, M.D.

THE following case of unusual surgical emergency, in operating for section of the sterno-cleido mastoid, deserves record as a warning. The patient was a girl of eight years, with wry-neck, with the usual contraction of the sterno-mastoid muscle. It was decided to divide that muscle by an open incision. The incision was made in the usual way, half an inch above the clavicle, the skin and platysma divided, and both sternal and clavicular attachments of the muscle incised. The head could now be straightened, but before the wound was sewed up, the finger was inserted into it and a small tense fibre belonging to the deeper portion of the muscle, which had escaped incision, was felt. It was thought advisable to divide this, to make a permanent correction more certain.

The fibre was therefore raised between two pairs of forceps, and an incision carefully made between them. A slight amount of venous blood came from the wound, but it was readily controlled by pressure-forceps. An attempt was made to ligate this point, but the ligature came away on irrigating the wound. This was followed by a recurrence of bleeding, which was not profuse, but persistent. Several attempts made at ligature were unsuccessful. No vein could be seen, and it was thought that the bleeding came from an anomalous vein lying in the muscular tissue close to the deep fascia. An attempt was made, by passing a needle, to secure the small mass of muscular tissue which appeared to overlie the bleeding-point. The hæmorrhage was easily controlled by pressure-forceps, but became quite profuse when the forceps were removed. It was then determined to carefully expose the bleeding-point by incision, and it was found necessary to incise the deep cervical fascia. When this was done, the blood was seen to come from a small incision in the internal jugular vein about an inch above the clavicle. The vein was distended about the size of a little finger. A bent probe was passed under the whole vein, with a silk ligature threaded through the eye end. This was carefully pulled through, and the vein was tied above and below the bleeding-point. The hæmorrhage then ceased, and the wound was sewed up. Aseptic precautions had been observed, and the wound healed, by first intention under the usual aseptic dressing. No disturbance followed the ligature of this vein. The patient recovered perfectly, with thorough correction of the deformity.

The case may serve as illustrating two points: (1) That, incising the deeper portions of the attachment of the sterno-cleido mastoid, it should be borne in mind how near they lie to the internal jugular vein, being separated from it (if the neck is straightened) only by the layer of deep fascia. (2) That, in dividing any remaining contracted fibres, the deep tissues should not be raised by forceps, as a portion of the vein may readily be pinched and raised also.

It would also appear from this, that thorough division by a tenotome of all the contracted fibres must be a hazardous procedure; for, if wounding of the artery is a possible accident in an open incision, where reasonable care is used and the parts are more or less under inspection, the danger would be greater if a tenotome were freely and thoroughly used. The imperfect division of the muscular attachments by tenotomy is probably not uncommon, and may explain the failure of attempted correction after tenotomy, and the necessity of prolonged mechanical correction.

[1] Reported at the meeting of the Surgical Section of the Suffolk District Medical Society, May 1, 1889.

Reports of Societies.

SURGICAL SECTION OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

G. H. MONKS, M.D., SECRETARY.

MEETING, Wednesday evening, May 1st, DR. E. H. BRADFORD in the chair.

An enormous

MULTILOCULAR CYSTOMA OF THE OVARY,

which had been removed by DR. JOHN HOMANS was shown, and the history of the case related by DR. JOHN HOMANS, 2nd.

The patient, a woman of seventy-four, had suffered from a tumor for about ten or twelve years, and had been tapped half a dozen times. The fluid in the cyst weighed seventy pounds, and the cyst-wall seven pounds. Photographs of the patient before operation were also shown.

DR. JOHN C. MUNRO read a communication on

THE TREATMENT OF MALIGNANT GROWTHS BY ESCHAROTICS.[1]

DR. J. C. WHITE said that his experience with the use of caustics in malignant disease of the skin had been principally confined to nitric acid, with which, however, he was thoroughly satisfied in all cases in which such methods or treatment were appropriate. He applies the acid on a pointed stick of wood, with which he bores well into the diseased tissues. He considers such an escharotic treatment of value in those superficial forms of epithelioma only, which frequently appear on the face and hands. A growth involving the deeper structures he refers to the surgeon for excision.

DR. G. W. GAY said that his first experience with escharotics for removing malignant growths was with arsenical paste, which had been recommended by Dr. Marsden. Dr. Ingalls gave the method a trial, but abandoned it on account of the pain, which was sometimes so excessive as to require full doses of opium. The slough which was formed was apt to be quite large.

Dr. Gay had used liquefied carbolic acid, with some oily substance, with considerable benefit. The pain was not very severe; and, when the slough separated, a clean, deep ulcer was left. He had found this application very satisfactory in the treatment of flat growths, as upon the face. Now, however, he uses caustic potash. The pain is not great, and the action of the caustic can be limited by acids, and the growth while small can be kept well under control. Recurrence is pretty certain, but the treatment can be repeated. Care should be used in selecting proper cases for this treatment. He would not use it in growths larger than the thumb nail. On the whole, perhaps,

[1] Publication deferred.

the very best thing to do is to remove the growth with the knife, and apply the caustic afterwards.

DR. J. C. WARREN had used nitrate of silver in a large number of cases after curetting. The stick should be bored into the growth in various places. He had, in office practice, occasionally used the Pacquelin cautery, after having injected cocaine. He always endeavored to inject the cocaine as near as possible to the source of the nerve supply, rather than into the growth itself. He had found, however, that all the caustic he had used in the more malignant epithelial types of face and hands, had only a palliative effect, and he considered the knife better.

DR. M. H. RICHARDSON did not believe in the use of caustics, except in the most superficial forms of malignant disease. He considered the process painful, clumsy and not thorough. He thought that caustics, which are only temporizing means anyway, are often used at just the time when the knife might do some permanent good.

DR. E. O. OTIS spoke of the deformity which might result from the use of caustic in careless hands, and referred to a case of cancer of the lower lip, which had been cauterized extensively with apparently a good result, but with a very disfiguring scar.

DR. RICHARDSON reported a

CASE OF REMOVAL OF FOREIGN BODIES FROM THE KNEE-JOINT.[2]

DR. WARREN called to mind how much in old days any operation in which the knee-joint was opened was dreaded by the surgeon; but that, now, with strict antiseptic precautions, the danger of bad result is not great. He spoke of about half a dozen cases which had recently been operated upon at the Massachusetts General Hospital, with the greatest success.

To what an extent a patient with a movable body in the joint was disabled he had always been impressed, and he thought that any operation which offered a reasonable degree of success would be justifiable. The surgeon should not forget, however, that occasionally adhesive inflammations in the joint glued down the foreign body to the walls of the joint, thus effecting a cure. Dr. Warren related a case in which this occurred.

DR. RICHARDSON spoke of the importance, in all such operations, of keeping the hands and particularly the nails, strictly clean surgically.

DR. SCUDDER spoke of the antiseptic methods employed in Roosevelt Hospital, in New York, which he had recently visited.

DR. BRADFORD described, in detail, the methods of Esmarch, in Kiel.

DR. BRADFORD then reported a case of

REMOVAL OF LOOSE CARTILAGES FROM THE KNEE-JOINT,

and said: The following case illustrates the origin of loose cartilage in the knee-joint. The patient was a man of fifty years, who had had symptoms of loose cartilage in the knee-joint for several years. One of these bodies could be readily felt to the outside of the patella, and an operation for its removal was undertaken. It was easily found and removed. On exploring the knee-joint with the finger, a second body was found inserted on the synovial membrane, beneath the quadriceps tendon. This was gradually separated by careful pressure with the finger, and removed. A third bit of cartilage, of the size of a ten-cent-piece, was found firmly imbedded in the synovial wall, and it could not be removed without undue violence. It was, therefore, allowed to remain. The wound healed perfectly, aseptic precautions having been taken and the joint irrigated. In a few weeks the patient recovered entirely, with perfect motion at the knee-joint, and with disappearance of his previous symptoms.

Dr. Bradford also reported a

CASE OF LIGATURE OF THE INTERNAL JUGULAR VEIN.[3]

DR. WARREN said that he fully realized the danger of wounding the vein. He recently operated on a case of wry-neck, and as he was about to divide the last fibres of the sterno-mastoid, the child coughed, and the incision laid bare the vein at once.

DR. RICHARDSON spoke highly of the open incision as recommended by Dr. Bradford in a paper read some months ago, and stated that since that time he had used that method only. There was less danger of wounding the vein than in subcutaneous tenotomy. He had frequently noticed in the dissecting room that, if traction is applied to a vein it loses its characteristic appearance, and appears like a band of fibrous tissue. He had abandoned the use of scissors near veins, and merely pressed the knife down upon the tense tissues, (without drawing the knife), in which case the fibrous tissues only are divided, and the vein slips out of the way.

DR. BRADFORD stated that he believed many cases which were operated on by the subcutaneous method were only half cured, the surgeon hesitating to divide the last few fibres of the sterno-mastoid.

DR. F. H. HOOPER showed a

RHINOLITH

which he had recently removed from the nose of a woman of fifty. For twelve years the patient had suffered from pain, and discharge from the left nostril, as well as obstruction. The septum was deflected to the right. The stone weighed five grammes and ten centigrammes. No nucleus could be found.

[2] Publication deferred.

AMERICAN NEUROLOGICAL ASSOCIATION.[1]

SECOND DAY — MORNING SESSION.

THE President, DR. E. C. SEGUIN, in the chair.

DR. GEORGE W. JACOBY, of New York, opened with a paper entitled,

A CONTRIBUTION TO THE STUDY OF ANÆSTHETIC LEPROSY, WITH SPECIAL REFERENCE TO PARTIAL SENSORY DISORDERS.

The points to which particular attention should be paid in all cases were, the electrical excitability of the muscles, the condition of the reflexes, the presence or absence of fibrillary twitchings, and the condition of sensation. Upon these data depended the diagnosis between anæsthetic leprosy and syringomyelia, as well as that of the central or peripheral localization of the leprous process. The conclusions arrived at by the author from the analysis of his own and other cases were that the differential diagnosis between the two

[1] Concluded from page 190 of the Journal

[2] See page 204 of the Journal.

diseases could not always be made; that partial sensory disorders are not characteristic of syringomyelia, but may occur in anæsthetic leprosy as well as in purely peripheral affections; and finally, that a differential diagnostic point between central and peripheral loss of temperature sense may lie in its complete loss in the one case and its partial loss in the other.

DR. STARR said that the same question as to the differential diagnosis between syringomyelia and anæsthetic leprosy had only recently occurred to him. Three weeks ago he had seen a case with Dr. Prince A. Morrow, of New York, in which there had been a gradual onset of an atrophic and anæsthetic affection of the right arm. He came from the Sandwich Islands, and had been exposed to leprosy. There was anæsthesia to temperature and pain, but not wholly to touch along the hand and part of arm. There were three small reddish brown spots on the arm which Dr. Morrow considered leprous in character. The idea of syringomyelia at once occurred to him, but the history of exposure in a leprous country sufficed to make anæsthetic leprosy at least the more probable nature of the disease; but without such history it would have been almost impossible to make the diagnosis. As to the matter of partial loss of sensation, in the cases of multiple neuritis and *beriberi* he had seen, the sensory loss was complete, with the exception however of muscular sense.

The PRESIDENT remarked that he had now under observation a case of leprosy, but had as yet made no careful examination of the temperature sense. His case illustrated the case of diagnosis at an early period, when confusion with syringomyelia could not occur. The patient had a wine-colored eruption on the entire left leg and part of the thigh, the foot being free, and there were three or four similar spots on other parts of the body. There was distinct analgesia and some anæsthesia in these areas, but there was no paralysis or atrophy. The patient had come from the Sandwich Islands. The well-defined limitation of anæsthetic areas showed that it could not be neuritis. Of late the anterior leg muscles had become paretic, but there was no reaction of degeneration. The left hand was beginning also to manifest similar symptoms. There were no ulcers.

DR. C. K. MILLS had seen two cases of leprosy. He thought the author's point with regard to partial sensory disorder very interesting, but he did not see why there should not be partial disturbance also in neuritis, and in fact in traumatic neuritis it was quite frequent. The nature of the sensory disturbance depended upon the extent of the injury to the nerve. In ordinary multiple neuritis it might be true, as Dr. Starr insisted, that there was complete loss of sensation, through destruction of all the sensory fibres. He did not see, however, why the sensation to cold should not be injured as much as any. It should be borne in mind that in all infectious diseases attacking the nervous system, there was a tendency to seize upon the central as well as the peripheral portions at the same time.

DR. GRAY agreed with the last speaker as to partial sensory disorders met with at times in peripheral neuritis. He had observed it also in multiple neuritis, where for instance there was impairment of touch and temperature sense, yet the pain was excruciating. He did not see that it was easy to diagnosticate syringomyelia, and Wichmann and Starr had given no rules for diagnosis in their pamphlets. He believed that no one had made a diagnosis of syringomyelia in life.

DR. STARR stated that Schulze had made the diagnosis in three cases, which had been substantiated by autopsy. The points for diagnosis were the general conclusions drawn from a study of collected cases. Anna Baumler had brought together 116 cases, to which thirty or more had since been added.

DR. GRAY thought that these diagnostic points would apply to many other spinal lesions.

DR. BIRDSALL had had similar ideas to those of Dr. Gray as regarded the diagnostic indications in syringomyelia until he had read Roth's collection of cases — in a certain number of such cases there were clinical pictures differing altogether from other spinal lesions and from peripheral neuritis. Disturbance of the temperature sense was the particular characteristic. Still the testing of this sense had been constantly neglected in studying other spinal cases, and it was possible that it might often be disturbed in other spinal disorders. It was hard to see how any other lesion could produce precisely the same symptoms as those of syringomyelia. It was a question whether tracts for temperature and pain could be localized in the cord. Peripheral nerve lesions might cause injury to some sense fibres and not to others, although generally all are injured, particularly where the inflammation is truncal in character. There might be partial sensory disturbance in dermal forms.

DR. GRAY said it was easy to localize disease in the anterior cornua, in the lateral and posterial columns of the cord, but the diagnosis of central lesions was very difficult. The fact that out of 150 cases of syringomyelia only three had been diagnosticated during life proved the truth of his assertion. The diagnostic suggestions given were therefore empirical. The presence or absence of temperature sense had not been sufficiently tested as yet. How would one distinguish a chronic central myelitis?

DR. BIRDSALL stated that central myelitis began acutely, and thus differed from the slow advance of syringomyelia.

DR. MILLS thought the question of partial sensory disorder most interesting. But he thought that there would be more apt to be partial disturbance in a truncal neuritis than in a dermal.

DR. PETERSON asked the President if the tendon reflexes were exaggerated in his case of leprosy, and was answered in the affirmative. He had asked this because he had recently read an interesting study of the reflexes in anæsthetic leprosy made by Dr. Suzuki of Tokio, and published in the *Sei-a-Kwai Medical Journal*, in which there was an analysis of seventeen cases; one had normal reflexes, while all the others had increased tendon jerks, and in some of the cases there was even ankle clonus. The conclusions arrived at by the author were similar to those of Dr. Jacoby.

The PRESIDENT called attention to the fact that so many cases of leprosy were now being continually imported into the United States, it seemed as if the country were threatened with its domiciliation. It was a question whether it was not the duty of physicians having such cases to report them to the authorities.

DR. SINCLAIR mentioned the recent presence of two cases in Philadelphia. The physician in charge had been fined by the Board of Health for not reporting them.

DR. PRINCE wondered at the manner in which lep-

rous patients were allowed to go about, and thought also that the attention of the authorities ought to be called to the disease, and reports to the Boards of Health ought to be required.

DR. GRAY knew that in the East where the disease is prevalent, isolation is practised. He wished to know what the actual danger of contagion was.

DR. BRILL said that the attention of the New York Board of Health had already been called to the matter.

DR. JACOBY, in closing the discussion said that Schulze was altogether too positive in his assertions. This author went so far as to contend that cases of leprosy where cavities had been found in the cord were not leprosy at all, but syringomyelia. As for himself he thought a central lesion probably often exists in this disease, although it is well known that the essential pathology lies in a truncal neuritis. A simple dermal neuritis could not be assumed in leprosy. In his case for instance the indurated and swollen ulnar nerve could be distinctly felt. He did not agree with Dr. Gray that the diagnosis of syringomyelia could not be made. The only danger lay in mistaking it for leprosy. He had only last evening come across a work of Suzuki, mentioned by Dr. Peterson, but had noticed the identity of the conclusions of that author with his own, although they were reached from different points of view.

DR. F. X. DERCUM, of Philadelphia, then presented two contributions entitled respectively

A DESCRIPTION OF TWO CHINESE BRAINS,
and
A NOTE ON THE PLI DE PASSAGE INFERIEURE INTERNE IN THE HUMAN BRAIN.

He exhibited the brains described. Dr. Mills had made morphological analysis of one in 1886, and descriptions of three Chinese brains had been added to literature by Moritz Benedikt. The six brains thus far analyzed exhibited unusual complexity due to excessive sinuosity of the gyri, and a tendency to excessive transverse fissuration. The frontal lobes were especially large and complex. There was unusual confluence of fissures indicative of a low degree of development such as is often seen in the negro's and sometimes in the white man's brain. There was unusual length of the parallel and Sylvian fissures, and eversion of the orbital and temporal lobes.

DR. MILLS said that it was very important to keep adding to our morphological descriptions of such brains, until accurate deductions could be drawn from a very large number.

DR. SPITZKA stated that the dictum that a tendency to confluence of fissures indicated a low type of development was not accepted by most anthropologists. The more brachycephalic the skull the greater was the development of transverse secondary folds. The elephant, which stands among the highest of mammals, had a broad skull and a tendency to confluence of fissures. The Chinese were not low in development. The internal pli de passage in the negro and idiot was significant only when the general cortical development was poor. The real cause of the location of the chief sulci lay in the inherent architecture of the brain, and was due to the arrangement of groups of cells and fibres, but the secondary and tertiary sulci might be influenced by other factors such as the course of vessels. While we might never be able to localize the higher functions of the mind, there was something in the physiognomy of the Chinese brain which struck him as differing altogether from that of the Caucasian. But it was not the same difference as was noticeable between the negro and Caucasian brains. The peculiar moral attitude of the Chinese pointed to some relation between the structure of their brains and the character of their minds. Still he had observed a great difference between these two Chinese brains, and there was no feature in them which might not be reproduced in the Caucasian brain.

DR. DERCUM had not wished to imply that transverse fissuration was indicative of a low type, but thought the unusual confluence showed a lack of cortical development. He did not consider them brains of a low type, but many features, such as were found in the brains of the negro and ape, were found here also. The excessive sinuosity, however, indicated a higher cortical development. For instance, in one brain there were five well-developed frontal gyri.

DR. SPITZKA had the same idea as Dr. Dercum. As compared with the Caucasian brain, the Chinese was in some respects inferior, and in others exhibited a superabundance of gyri. He spoke of the resemblance between negro and ape brains. The differences between the brains of the ourang outang and chimpanzee were greater than those between the brains of the chimpanzee and a human being. There was no uniform appearance of the ape's brains. Vogt and another had classified the human brain into three types, the negro, Mongolian and Caucasian, corresponding somewhat to the three lower types of the gorilla, chimpanzee and ourang outang.

DR. M. ALLEN STARR, of New York read a paper entitled

THE PATHOLOGY OF SENSORY APHASIA, WITH AN ANALYSIS OF FIFTY CASES IN WHICH BROCA'S CENTRE WAS NOT DISEASED.

In all of these cases collected by the author some form of sensory aphasia was present, and in all the lesion lay in the posterior lower third of the brain. In seven of the cases there was pure word deafness, and in these the lesion was limited to the posterior portion of the first and second temporal convolutions. In eleven cases there was pure word-blindness, and in these the lesions were found distributed either in the angular gyrus, the occipital lobe, the temporal convolutions or the inferior parietal region.

In seven cases word-deafness and word-blindness were co-existent, although the use of language was not lost; and in these the temporal convolutions were involved, extending in some to the inferior parietal, angular and occipital convolutions. The practical application of the localization of aphasia lesions is obvious, for the regions concerned in speech are especially accessible to the surgeon.

Another fact of interest is that it seems to be proven that there is no ideational centre. An idea may be impaired but cannot be wholly destroyed by a single cortical lesion. Thought being regarded as the play of consciousness, a long association of fibres between sensory centres cannot be localized.

DR. LLOYD had now a case of simple homonymous hemianopsia without psychical or word-blindness, and wished to know whether there was any diagnostic importance in this condition as to localization. Was there a preponderance of one hemisphere over another as regarded sensory memories of language?

DR. STARR said that the matter of psychical blindness had recently been discussed by Wornicke and another. A lesion affecting bilaterally both occipital lobes or the association tract produces psychical blindness, but a lesion along either tract itself does not cause this condition. Nine cases of psychical blindness from lesions of one hemisphere alone had been reported.

The election of officers for the ensuing year being then in order, the following were chosen:

President, Dr. E. C. Spitzka, of New York; *Vice-Presidents*, Dr. Wharton Sinkler, of Philadelphia, and Dr. H. M. Lyman, of Chicago; *Secretary and Treasurer*, Dr. G. M. Hammond, of New York; *Councillors*, Dr. Henry Hun, of Albany; Dr. C. L. Dana, of New York.

AFTERNOON SESSION.

DR. J. H. LLOYD, of Philadelphia, read a paper entitled

A LATER HISTORY OF A CASE OF FOCAL EPILEPSY FOR WHICH TREPHINING AND EXCISION OF THE MOTOR CENTRES WERE PERFORMED.

Full details of the case had been recorded at the last annual meeting of the Association. At that time but three months had elapsed since the operation, and Dr. Ferrier, of London, had stated in a discussion that the time was too short for a decisive result as to the usefulness of the operation. Now that more than a year had passed, further details could be given. Before the operation the patient had had many seizures daily. There was no fit for four months after the operation. Since that time however, there had been some ten seizures in nine months.

DR. SPITZKA said there was a minority, but a powerfull minority, of clinicians and physiologists who hesitate to accept the dictum that spasms were always of cortical origin when clonic in character and local in manifestation. There were well authenticated cases of spasms such as are generally described as cortical, which undoubtedly had their origin in the pons or medulla. He, therefore, thought it premature to advise surgical procedure when there was still doubt as to the position of the convulsive centre. He was of opinion that the seat of irritation in the great majority of cases of epilepsy was in lower centres, such as Nothnagel's convulsive centre.

DR. MILLS mentioned the case of a man subject to unilateral convulsions beginning in the hand. There was a scar upon the head, and trephining was done at this spot in order to relieve severe pain, probably due to trigeminal irritation in the scalp or dura. This operation relieved the pain, but caused the Jacksonian epilepsy upon the other side. The operation was repeated in the same spot, the membranes and cortex being removed to some extent, and with great success. It was an apparent illustration of the fact that convulsions may occasionally be the result of operations themselves.

DR. DERCUM had seen the same case and stated that the dura was not opened in the first operation. At the second trephination the membranes were found united. There was a pachymeningitis. The patient had surgical epilepsy. Six months elapsed between the operations.

DR. LLOYD said it was a question whether one could have localized epilepsy from irritation of lower centres, as Dr. Spitzka had intimated. He had always held the idea that such spasms were of cortical origin. In the case he had just described the absence of fits for four months led him to believe that he had removed the parts concerned in their manifestation. He had been hopeful of the efficacy of this method in the relief of such a disorder, and was not yet willing to give up the idea that something may be accomplished in this way. He thought it would be justifiable to operate again in this same case.

DR. SPITZKA asked if the cortex removed had been examined microscopically, and what was the pathological condition found.

DR. LLOYD answered that the microscopist had reported atrophy of the cortical cells.

DR. SPITZKA remarked that atrophied cells could scarcely be very potent in the production of epilepsy.

DR. LANDON C. GRAY, of New York, then presented a paper upon

THE DIAGNOSTIC SIGNS OF MELANCHOLIA.

in which he called particular attention to the difficulty of diagnosis of simple melancholia at times. It was usually when in mild degree confused with neurasthenia. He had recently made a study of eighteen cases of this form, and pointed out what he considered the three cardinal symptoms; namely, depression, insomnia and post-cervical ache. The last named he thought especially characteristic. This pain was sometimes neuralgic in character, at others vague and continuous. Simple melancholia, such as this, should not be confounded with neurasthenia, or melancholy states dependent upon hepatic or nephritic disease, or with nontypical forms of insanity.

DR. H. S. UPSON, of Cleveland, then read a paper in which he considered the relation between

MULTIPLE NEURITIS AND INFECTIOUS CEREBRO-SPINAL MENINGITIS.

Dr. Miils had first suggested the possibility of connection between the two. His own case was briefly as follows: A woman, age twenty-seven, had intense pain and tenderness in the extremities, with stupor and slight opisthotonos, no electrical examination could be made because of the extreme hyperæsthesia. She had had a multiple neuritis a year before but recovered. The autopsy revealed congestion of the pia of brain and cord with marked serous effusion, and a microscopic examination of the ulnar nerve revealed interstitial inflammation there. In the opinion of the author, the nerve trunk inflammation was not parenchymatous, but rather of the membranes, and was analogous to the process in the brain and cord; the nerve fibres were secondarily involved. He had not looked for bacteria.

Dr. MILLS naturally felt interested in the case. He had had an autopsy on one of his own cases. Portions of nerves and sections of the brain and cord had been examined by Dr. Gray of Washington, and this examination proved conclusively the association of neuritis with the cerebro-spinal meningitis.

DR. SPITZKA referred to the vacuoles in the author's sections, and said retarded lymph outflow might be important in causing the death of tissue and the formation of gas bubbles which these vacuoles must be considered to represent. He had noticed also two bodies in the section, larger than ordinary leucocytes, very delicately stained, which the author should have carefully delineated.

Dr. C. K. Mills, of Philadelphia, then gave an abstract of a paper by Dr. J. T. Eskridge, of Denver, on a

CASE OF ABSCESS OF THE BRAIN; OPERATION; DEATH ON THE NINTH DAY.

The patient had had typhoid fever. Two months later there was purulent inflammation of the middle ear, and not long after, symptoms of brain irritation followed, such as headache, delirium, persecutory delusions, together with paralysis of the right hand and right angle of the mouth. The skull was trephined over the face and hand centres, and a purulent inflammation was found under the dura. The wound was then dressed, and the patient died nine days later. A widespread suppurative meningitis was found at the autopsy. Dr. Mills thought the case of great practical value. He thought trephining should have been performed in two places, at the centre which had been properly localized and also over the mastoid region where the inflammatory process had originated.

Dr. B. Sachs, of New York, read a paper on the

PERONEAL FORM OF PROGRESSIVE MUSCULAR ATROPHY.

The author reiterated his statement of last year that this form was closely related to Duchenne's type. He gave very full details of the cases of two brothers that had recently come under his observation through the kindness of Dr. Gibney. The boys were thirteen and ten years of age. There was a gradual development of double club-foot in both at the age of five years, followed by an atrophy proceding upward, beginning in the leg and toe muscles and spreading to those of the thigh, in one case also involving muscles of the upper extremities. The knee jerks were present. In one there was general anæsthesia, in the other paræsthesia. There was full degenerative reaction in some of the muscles of one boy, partial in the other. The progressive wasting rendered treatment of this form of club-foot less satisfactory than that of congenital cases. He would suspect this peroneal form in all cases where acquired club-foot was associated with progressive wasting of the leg muscles, and particularly if heredity or family occurrence of the disease could also be established.

Dr. Sinkler could recall several similar cases, one in particular of two brothers. But doubtless more would be seen if careful attention were paid to the matter.

Dr. Birdsall did not think the presence of knee jerk so important a diagnostic point as the author seemed to regard it. He had seen a few cases of old poliomyelitis where the paralysis and atrophy were below the knee, and yet the knee jerks were quite active on both sides. It could not therefore be an essential point in diagnosis. Dr. Bullard had also observed the presence of the knee jerk in old cases of poliomyelitis.

Dr. Prince asked if the author had said that the absence of pseudohypertrophy was a diagnostic point between this form and primary myopathies, and was answered in the affirmative. He did not consider this true.

Dr. Spitzka asked if the symmetry and the coincidence of time and intensity as shown in the photographs were always the case, and was answered in the affirmative.

Dr. Sinkler corroborated two of the speakers as to the presence of the knee jerk in cases of old poliomyelitis, and cited an instance from his own experience.

Dr. Gray objected to the division of progressive muscular atrophy into groups. Why should there be an arm type, a face type, a leg type? Such division might be carried out indefinitely. A more useful classification would be upon the pathology of the disease, a division into central, muscular and peripheral nerve lesions.

Dr. Sachs said he did not lay great stress upon the presence or absence of the knee jerk. Yet in extreme atrophy of the vasti from poliomyelitis the knee jerk was always absent; and if it were present he should consider it a case of progressive muscular atrophy. He had himself tried to discard subdivisions as much as possible, but the present classification was a clinical necessity. A better might be made when the pathology is more accurately determined. At present there were spinal and non-spinal cases, but there was no certainty as regarded peripheral nerve cases.

Dr. Morton Prince, of Boston, then exhibited some microscopic specimens from the muscles of a case of

PSEUDO-HYPERTROPHY.

The patient was now twenty-eight years of age. The specimens showed a large quantity of connective tissue, hypertrophy of a few fibres, and great atrophy of many of the fibres. There was also great loss of striation, but no fatty or granular degenerations and no vacuolization.

The following papers were read by title:

A SERIES OF CASES OF CEREBRAL HÆMORRHAGE OF UNUSUAL INTEREST,

by Dr. J. H. Lloyd, of Philadelphia.

THE HISTOLOGICAL EXAMINATION OF NERVES REMOVED FOR TRIGEMINAL NEURALGIA,

by Dr. J. J. Putnam, of Boston.

THE PATHOLOGICAL ANATOMY OF CHOREA,

by Dr. C. L. Dana, of New York.

PARANOIA IN TWO SISTERS,

by Dr. Frederick Peterson, of New York.

The following new active members were elected: Dr. Hobart A. Hare, of Philadelphia; Dr. J. P. C. Griffith, of Philadelphia.

The meeting then adjourned.

In the evening a banquet was given by the Association at the place of meeting, the West End Hotel, at which some thirty members were present.

FIFTH DISTRICT BRANCH OF THE NEW YORK STATE MEDICAL ASSOCIATION.

Fifth Annual Meeting, held at Brooklyn, N. Y., May 28, 1889, the President, Wm. T. Lusk, M.D., in the chair.

MORNING SESSION.

ADDRESS OF THE PRESIDENT.

In opening, Dr. Lusk congratulated the Branch Association upon its prosperity, the rapid growth in membership, the zeal exhibited for the principles for

which the organization stands, and the scientific merit of the work performed at these annual gatherings, which he said were all prophetic of a long and useful life.

He then proceeded to narrate two cases which he had hitherto refrained from publishing, in order to present them first on this occasion.

I. LABOR AT FULL TERM: UNDILATABLE CONDITION OF THE CERVIX DUE TO CICATRICIAL TISSUE, SPONTANEOUS RUPTURE OF THE UTERUS.

The patient aged thirty-three years, was brought late at night to the Emergency Hospital, exhibiting signs of the most severe suffering. The temperature was 99½°, the pulse 140; and the woman was semi-maniacal. This was her second pregnancy, as far as could be learned. Her first confinement had been a prolonged one, and had been terminated by instruments. The present labor had then lasted about thirty hours. Dr. Lusk was hastily summoned, and on his arrival he found that the membranes had long been ruptured, the uterus was firmly retracted upon the child, whose body was apparently situated in an oblique position, with the head directed to the left, and rupture of the uterus seemed imminent. A digital examination showed that no dilatation of the cervix had taken place, and that this fact was due to firm cicatricial tissue situated at the internal os and extending somewhat over the lower uterine segments. With the impending danger of rupture, he decided upon the Cæsarean section; but the cries and importunities of the patient at sight of the preparations for the operation led to hesitation, and this hesitation proved fatal.

While the question of operation was under debate she called for a chamber, saying that she wished to pass urine; and when placed upon the vessel began, in spite of every attempt to control her, to make violent straining efforts. Suddenly she fell back unconscious. The pulse was almost imperceptible, and the entire surface of the body became intensely pallid, and covered with clammy perspiration. It was evident that uterine rupture had taken place, and the patient, who did not rally, died in almost two hours. The autopsy was made by Dr. T. Mitchell Prudden, and he reported that on making the abdominal incision the body of the child was found corresponding to the long axis of the mother's abdomen, with the back directed to the front, and the head bent sharply to the front. There was a considerable quantity of soft red blood-clot in the abdominal cavity, and the rent in the uterus extended obliquely across the uterus from the upper cervical portion to the right side of the fundus. The uterine walls were about one centimetre thick, and the ragged edges of the rent were deeply stained and infiltrated with blood. The placenta was firmly attached to the left upper segment of the uterus, which contained about sixty cubic centimetres of dark soft blood-clots. The os externum was lacerated from the previous labor, the upper portion of the cervical canal was narrowed by dense cicatricial tissue, so that its diameter was about two centimetres; and the anatomical diagnosis therefore was: Rupture of the Uterus, with old firm cicatricial contraction of the Cervix Uteri.

The case was rare, Dr. Lusk said, inasmuch as the cicatricial contractions were situated at the internal os and the lower uterine segment. Dilatation by incision or other antiseptic means was impossible. When cicatrices were limited to the lower part of the canal, as was usually the case, the obstacle to the birth of the child was usually removed by the employment of the knife to sever the limiting bands. Again, the case furnished a new illustration of the fact that in spontaneous rupture the laceration is not of necessity confined to the thinned lower uterine segment, as has been maintained by some of the extreme partisans of Bandl's theory.

He thought that the early performance of the Cæsarean section or the Porro operation would probably have saved the patient's life; although at the late period of her admission to the hospital either procedure would have partaken of the nature of a forlorn hope. Spontaneous rupture during labor, he went on to say, is not so rare an event that those engaged in busy practice can afford to be ignorant of the means of combating the tendency to a fatal result by all the resources of modern science. To Bandl belongs the merit of showing that nearly all ruptures begin in the lower uterine segment. In normal labors during each pain the fundus and body of the uterus thicken, while the lower segment is stretched and thinned by the ovum or the presenting part of the fœtus. So long as no obstacle is met with which hinders the descent of the ovum or the fœtus, this process ends in the conversion of the uterus and vagina into a continuous canal. Ordinarily, in advanced labor, the lower circumference of the body is distinguished from the stretched lower segment by a thickened ridge termed the contraction ring, or ring of Bandl, though in easy labors this ring is often but slightly indicated.

When, however, the descent of the fœtus is hindered by any cause the resistance of the ligaments which hold the uterus in position is overcome by the continued retraction of the fundus and body, and, as a consequence, the contraction ring is withdrawn upwards, the lower segment is thinned, and, in extreme cases, nearly the entire uterine contents may occupy the distended passive inferior segment. Under these circumstances the contraction ring is strongly marked, and may be felt through the abdominal walls above the pelvis, or even in the neighborhood of the umbilicus. This movement upward of the contraction ring is limited somewhat by the pelvic and round ligaments and by the direction downward of the abdominal pressure; and as these restraining agents operate more efficiently in first than in subsequent labors, it is not difficult to comprehend the relative frequency of rupture in women who have borne many children. As a result of the continued retraction of the body of the uterus the lower segment may become so distended as to form little more than a membranous covering to the fœtus, and the conditions favoring rupture are established. It has been maintained upon theoretical grounds that spontaneous rupture is arrested by the contraction ring, and this is certainly the rule where there has been no art intervention; but the case in question shows that the rule has its exceptions.

Undoubtedly the popularization of Bandl's teachings has contributed greatly toward the adoption of an intelligent prophylaxis in difficult labors. The situation of the contracted ring, which, when well defined, can usually be felt through the abdominal walls, furnishes in many cases an index of the degree of the threatened danger. The risks are further increased in cross births, in hydrocephalus of the child and in lateral and anterior displacement of the uterus, ow-

ing to the augmented pressure exerted under such conditions upon a limited portion of the already over-distended tissues. If rupture occurs under these circumstances the accoucheur cannot wash his hands of responsibility. He ought to know that the faulty uterine positions should have been early connected by judicious bandaging, the hydrocephalic head reduced by puncture, and that in all forms of obstructed labor there comes a time when patient waiting ceases to be a virtue and active intervention is demanded. The new learning teaches us that when the uterine efforts have proved unavailing to fix the presenting part, and the increasing distance of the contraction ring from the pelvic brim points nearly to a dangerous thinning of the uterine muscle, the physician must decide promptly upon the indicated measure of relief. These, in head presentations are version, craniotomy and the Cæsarean section. In neglected shoulder presentations only, cautious attempts at version are justifiable, and the operator should never forget to support the head with one hand through the abdominal walls in such a way as to relieve the strain upon the over-distended tissues. In case of failure the persistent use of rude force is criminal.

Dr. Lusk stated that his object in dwelling upon these points was the fact that he did not believe that rupture of the uterus is by any means so rare as statistics would seem to indicate. While, however, insisting upon a rule of personal accountability as regards the accoucheur, he said it was necessary to recognize that to Bandl's scheme there are exceptions. Now and then, cases are reported in which primary rupture has occurred in the fundus and in the body, and where the lower segment has given way without antecedent signs or warnings. Having mentioned such a case in his own experience, he said that rupture may be complete or incomplete. In the latter the tear is confined to the muscular structures, and the peritoneum remains intact. In most instances the hæmatoma resulting from the bleeding vessels dissects up the peritoneum for a certain distance beyond the tear. In the complete form the peritoneum likewise gives way, but to a less extent.

When the shock, the sudden stoppage of the uterine pains, the recession of the presenting part, the bloody discharge, the lateral tilting of the fundus, or its apparent disappearance in the case of the passage of the entire child into the abdominal cavity has led to a diagnosis of rupture, the first indication for treatment is the speedy removal of the child. In selecting the manœuvre for accomplishing this, the important consideration to be kept in view is that it shall to the least possible extent increase the dimensions of the already existing rent. In general terms he said it might be stated that with an undilated cervix, or in cases of extreme pelvic contraction, or after the passage of the head and arms through the rupture, and in all cases where the child passes entirely into the abdominal cavity, laparatomy is the more conservative measure. There is not only less shock, but the opening of the abdomen enables the operator to remove effused blood and amniotic fluid from the peritoneal cavity. Still, the not uncommon impression that the ruptured uterus furnishes a promising field for abdominal surgery does not take into account, that in many of the cases where laparatomy is clearly indicated the patient is practically moribund.

The employment of the suture to close the uterine wound in view of recent Cæsarean processes seemed reasonable, but it was to be borne in mind that with ragged borders infiltrated with blood, with the peritoneum stripped off, and sometimes with air infiltrated into the sub-peritoneal connective tissue, the conditions for union are in no way comparable to those which exist in Cæsarean section. The Porro operation, he thought, promised better results, though the deep situation of the tear would make it difficult to secure a healthy pedicle. There should, however, be no hesitation about the suturing of the peritoneal surfaces, as the rupture is thus converted into an incomplete one, with its more favorable prognosis.

When the child could be removed by the natural passages without increasing the extent of the rupture, and when the latter was confined to the lower segment, he considered laparatomy of doubtful value. In many such cases recovery as far as life was concerned had been secured by the employment of antiseptic irrigation and filling the gap with antiseptic gauze. At the same time drainage should be secured by means of iodoform wicking or the bent rubber tube, both drainage and packing being most effective when the tear is situated in the posterior wall. This plan of treatment is, of course, only useful where no infection of the abdominal cavity has taken place at the time of the rupture, and the best results are obtained, therefore, in cases of complete rupture. At the same time that drainage is used, compression of the fundus and body should be employed by means of the hands through the abdominal walls, and in case of hæmorrhage efficient aid can be furnished by pressure made upon the aorta. It may be necessary to maintain manual compression for hours. Finally, a carefully-graduated compress should be placed around the uterus to maintain firm contractions. For this purpose he prefers the disc-shaped hydrostatic bag partially filled with water; and in this condition and in all forms of post-partum hæmorrhage he has found it most effective. It adapts itself nicely to the contour of the contracted uterus, and it has sometimes seemed to him to work as intelligently and surely as the skilled hands of the accoucheur.

The second case was one of Cæsarean section resulting fatally. The patient had a contracted pelvis and kyphosis, with an abscess from which there was a large accumulation of pus under the psoas muscle, and Dr. Lusk expressed the opinion that if in this instance he had performed the Porro operation, and thus by the removal of the uterus relieved the pressure upon the intestines and other structures, the patient's life would probably have been saved.

Dr. Thomas H. Manley, of New York, read a paper on

THE GENESIS OF TUMORS.

Dr. F. E. Martindale, of Port Richmond, Staten Island, read a paper on

CALCIFICATION OF CARDIAC LEFT VENTRICULAR WALL FOLLOWING SUBACUTE VERRUCOSE ENDOCARDITIS.

This case, he said, was first reported in the "Transactions of the Medical Society of the State of New York," for the year 1887. The patient, a man aged seventy-three years, was suddenly attacked, April 13, 1886, after half an hour's ride, with intense pain in the precordial region, accompanied by a cold perspiration and dyspnœa with a sense of impending dissolution. After three hours of active treatment

partial relief was secured, but the dyspnœa remained as a permanent symptom of some serious derangement of the circulatory apparatus. Dr. Martindale was called to the case April 15. The general appearance of the patient was indicative of exhaustion. The face was flushed and anxious; the temperature 101½°, and the pulse 100, weak, and intermitting every third beat. There was an occasional dry cough, and auscultation revealed some coarse râles at the base of the left lung and an indistinct friction sound near the junction of the third and fourth ribs with the sternum. The respiratory murmur was exaggerated over the middle and lower lobes of the right lung, while the upper part of the left lung was less resonant on percussion. The cardiac area was moderately enlarged laterally and upwards, and the apex beat was scarcely perceptible, a feebly pronounced purring sound taking its place. There was a marked epigastric tenderness, and the area of hepatic dullness was enlarged.

The diagnosis made was subacute endo-carditis, with circumscribed peri-carditis at or near cardiac base. The etiology was obscure, as there was no history of either acute or chronic rheumatism or nephritis or any exanthematous disease since childhood. Under appropriate treatment there was a gradual abatement of the symptoms and of the physical signs, with the exception of the friction sound, which remained and seemed more distinct than at the onset of the attack, demonstrating, as was believed, an extension of the imflammatory process from the serous lining of the pericardium to that of the left lung. By April 27 there was an intermitting of only one beat in seven; the systolic impairment being supposed to be due to a mitral insufficiency. By May 1st, the intermission of the heart-beat had entirely disappeared, but the apex murmur still remained as a symptom of endo-cardial irritability.

The dyspnœa, which had been the cause of the patient's chief distress, ceased, and the relief experienced from its disappearance, with an improved appetite, encouraged the hope of permanent relief from his disability, when on May 3d, Dr. Martindale was hurriedly sent for on account of sudden and severe pain in the right fore-arm. Examination showed the right hand cold and livid, and the radial pulse absent, that of the brachial at its bifurcation being full and regular. A curious complication in connection with this complication was the alteration noted in the supposed mitral bruit, which had been previously quite pronounced. Thereafter it became much less distinct, while the force of the cardiac contraction was increased. The lesion was at once diagnosed as an embolic infarction of the right radial artery; the point of occlusion being at or near the brachial division, as manifested by the lividity and low temperature of the forearm, and the combined numbness and pain referred to the elbow. Subsequently the patient had two attacks of marked dyspnœa, with pain in both legs and œdema of the feet and ankles. By the 1st of July a very appreciable improvement had been again inaugurated; but it was not until the early part of August that the rythm of the right radial artery had become at all comparable with that of the left. In the meanwhile but slight modifications of the precordial bruit were observed.

From a careful inquiry into the previous history of the patient it was learned that in June, 1873, he had been suddenly attacked with a series of symptoms, alarming in their intensity as those of the initiatory stage of the then existing disability, and that a diagnosis of some cardiac lesion, the precise nature of which could not be obtained, was made by the physicians in attendance.

The history of the case thus given was that presented at the meeting of the New York State Medical Society referred to. By August 1st, the patient's general health and the distressing symptoms from which he had been suffering were greatly improved; but the auscultatory evidences pointed to a chronic mitral insufficiency, representing probably, to some extent at least, the first, and certainly, to a much greater degree, the last endo- and peri- cardial attacks, and it was now clear that even should he survive for any length of time, he would unquestionally labor under a permanent cardiac insufficiency, with more or less remote compensatory hypertrophy and dilatation and the functional disturbances resulting therefrom. In December, œdema of the feet and ankles reappeared; the cardiac insufficiency recurring again progressive, with its accompanying dyspnœa, and pericardial line of dulness again rising. Subsequently the patient's disabilities were again relieved to a considerable extent, but by the following April œdema of the lower extremities was again on the increase. The percussion note over the lower third of the pericardial triangle was flat, and the indications generally pointed to a gradually progressive infiltration of the connective tissues. By July 3d, the œdema had extended to the middle third of the thighs and implicated the scrotum and prepuce, while dyspnœa had again become so serious as to render the recumbent position impracticable. By the middle of September the anasarca had become general, and the patient died from œdema of the lungs on October 23d.

At the autopsy there was found general anasarca, with a considerable hæmorrhagic effusion in the pericardium. The apex of the heart was drawn backwards, and was firmly attached to the middle lobe of the left lung; the adhesions involving the two layers of pericardium and pleura. The left ventricular wall had undergone calcareous degeneration, and was very thin at this point. There was considerable cardiac hypertrophy and dilatation, but no valvular lesions were found, with the exception of a single tendinous spot on one of the mitral folds, if that could be regarded as such. The original diagnosis was at fault, therefore, only in attributing the apex murmur to a mitral stenosis, rather than to a roughened and unyielding endocardial surface.

In reviewing the history of this rare case, Dr. Martindale said some important questions relating to the etiology of this lesion arose. (1) Was the initial attack, in 1873, an endo- or peri- carditis, and to what degree were either or both attacks concerned as factors in the subsequent permanent calcareous degeneration? Although the history did not make this apparent, there must have been an etiological factor behind the first attack, since all leading authorities agree that primary idiopathic pericarditis is of extremely rare occurrence. In regard to primary endocarditis, also, there is absolutely nothing known of a positive character. We are, therefore, forced to the conclusion, that the cardiac disability of 1873, in this case, must have had its origin in either a rheumatic or an exanthematous lesion at so early a period in the patient's life that it produced no permanent impression. There could be little doubt, he thought, that the first lesion, in 1873, was a circumscribed pericarditis, with a possible implication,

to a limited extent, of the muscular tissue of the heart. In the initial stage of an acute pericarditis marked derangements of respiration are noticed, particularly if the cardiac muscular tissue becomes involved. Severe pains in the chest and epigastrium have also an influence in determining the degree of dyspnœa; and these, together with the pressure of the pericardial effusion upon the heart, are usually quite sufficient to establish the cyanotic and collapsed conditions so frequently observed in these cases, and which were the marked features of the one under consideration in its early development. Upon a careful examination of the specimen, he said it could be seen that the endocardial surface of the calcified ventricular wall was smooth and polished, while the myocardium was the chief seat of the calcareous deposit; which further tended to substantiate the view that the disability of 1873 started as a pericarditis, but that the myo- and endo- cardium were not seriously implicated until the recurrence of 1886, for it was hardly to be regarded as possible that the pathogenetic conditions of the latter date (even though greatly modified in degree, as compared with those observed in the specimen) could have existed thirteen years without any subjective symptoms whatever.

Another interesting question, he went on to say, had reference to the etiology of the embolic infarction of 1886. For this, there was needed no more reasonable hypothesis (assuming the myocardial lesion existing at this period to have been a sequence of the secondary pericarditis of 1873), than that the left ventricular pericardium was at this time attached by circumscribed adhesions to the left pleura; its contractile power being not only restricted by this, but likewise by the gradual degeneration of the cardiac muscular tissue as well. The blood current through the left ventricle must have been churned, as it were, by the irregular and imperfect contraction of its normal muscular fibres upon the dense and non-contractile myocardial wall; and from this resulted, no doubt, the formation of a small coagulum and its subsequent localization, through the innominate, right subclavian, and brachial arteries, at the seat of the radial infarction.

At this point, he said, the inquiry forced itself upon us as to the possible agency of sepsis in the etiology of cardiac embolism as illustrated in the case before us; and, having referred to several modern authorities, he stated his conviction that it was clear that nothing positive could be affirmed regarding sepsis as an etiological factor in the remarkable cell metamorphosis observed in this specimen.

In conclusion, Dr. Martindale said that the etiology of the tissue change resulting in the calcareous degeneration, involved a question of more than ordinary scientific interest. The hypothesis would seem to be a reasonable one, that its starting-point, in the earlier attack, was the visceral layer of the pericardium, the myocardium having been involved in a slight degree only. The lesion, in the course of the year's disability, became chronic, and finally terminated in resolution, with compensation and measurably impaired cardiac contractility, under which a fair degree of health was enjoyed for thirteen years, from June, 1873, to April, 1886. At the latter date, the etiological factor must have been a subacute endocarditis, with possibly circumscribed pericarditis, subsequently implicating the interstitial and connective tissue of the myocardium. That the endocardium must have been involved early in the second attack, the blood-clot and radial infarction would seem to have established positively; but it could only have been in the later stages of that attack that the circumscribed myocardium became wholly destroyed by tissue metamorphosis, with the resultant thin long septum seen in the specimen.

(To be continued.)

Recent Literature.

A Manual of Diseases of the Ear, for the use of Students and Practitioners of Medicine. By ALBERT H. BUCK, M.D. Clinical Professor of Diseases of the Ear in the College of Physicians and Surgeons, New York, etc. Octavo, pp. 411. William Wood & Co. 1889.

The present work is a modification of the author's Diagnosis and Treatment of Ear Diseases, published in 1880, and we must say very much improved in every way. It has been rearranged, in many places rewritten, is much more systematic than the previous work, and constitutes now a manual of great value.

Anatomy and physiology are treated briefly and well in an appendix only, the book itself being given up to a thoroughly practical treatise in which etiology, pathology and treatment are the prominent features, and many illustrative cases are cited. All subjects are discussed with candor, fairness, without dogmatism, and throughout the book there is a personal flavor which brings one in close and pleasant relations with the author, and reminds one of Watson's Practice, in which this characteristic was so marked as to make that work one of the delights of our student days.

Obstetric Aphorisms for the Use of Students Commencing Midwifery Practice. By JOSEPH GRIFFITHS SWAYNE, M.D. Ninth edition. 16 mo., pp. 159. Philadelphia: P. Blakiston, Son & Co. 1888.

The appearance of the ninth edition of this well-known book attests its continued popularity. It is a pity that in this edition there should not have been incorporated the most recent and improved teachings in regard to aseptic obstetrics, and that clear and explicit rules should not have been given for the student's guidance. The section on puerperal fever is painfully inadequate and antiquated. But in spite of these defects, which must be remedied by the teacher, the book is of great service to students who begin their clinical work in obstetrics before they have received a full course of didactic instruction.

Questions and Answers on the Essentials of Obstetrics, prepared especially for Students of Medicine. By WILLIAM EASTERLY ASHTON, M.D. 16 mo., pp. 220. Philadelphia: W. B. Saunders. 1888.

The object of this little book is indicated by the title. It is based on Parvin, Lusk, Playfair, and other standard authors, and will no doubt prove useful to students in preparing for examination. The book is neatly printed and bound, and has a good index.

—We notice in the northern papers an advertisement of an estate for sale in Virginia, with the following comprehensive statement of hygienic advantages, "Location for climate, health, lungs, rheumatism and asthma unsurpassed."

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 29, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

FŒTAL MALARIA TRANSMITTED BY THE FATHER.

THE very considerable susceptibility of the fœtus in utero to various diseases, infectious and otherwise, has been naturally most widely associated with conditions of the maternal organism, from the fact of the long-continued and intimate connection of the child with the mother as compared with that which it has with the father. The mother's power for infecting the fœtus is, in other words, twofold; namely, by a vitiated ovum, and also *post conceptum* by influences operating through the placental circulation; while the father has but one such opportunity, namely, by a vitiated spermatozoon.

In the case of one malady, syphilis, it is held by most authorities that the infection of the fœtus may be conveyed solely by the father, the mother remaining uninfected unless by the syphilitic occupant of her uterus.

Tuberculosis, if inherited, shows itself so much later than syphilis as greatly to complicate the problem of its transmission. A few instances in the human subject and in the calf seem to show that the bacilli can traverse the placenta from the maternal organism, and though Cohnheim, with others, taught that tuberculosis was transmissible in the semen and in the ovum, it must be confessed that the drift of recent opinion is against its being conveyed in the generative element of either parent, or at least of the male.

It is possible that in the study of fœtal malaria we may find an aid to the solution of some of these problems of pathological inheritance. For we have here a disease at once infectious and chronic, and like syphilis rather than tuberculosis, early in its manifestations after birth. The existence of fœtal malaria has been sufficiently demonstrated by the observation of interuterine and neonatal chills, accompanied by an enlarged spleen, occurring in the child of a similarly affected mother. If she was infected at the time of conception, she was obviously infected throughout the pregnancy, so that the transmission of malaria *per ovum* could not be demonstrated, because such transmission *per placentam* could not be eliminated. So far as we recall, no instances have hitherto been recorded where the child showing malaria, the father alone of the parents has had the disease.

We find, however, in the *Edinburgh Medical Journal* for June, two cases of great interest in this connection, recorded by Dr. R. W. Felkin, Lecturer on Diseases of the Tropics and Climatology, in the Edinburgh School of Medicine. In both, the father had well-marked malaria, and the mother was free from it; yet the child showed symptoms of the infection.

In the first case, the husband had contracted, on the west coast of Africa, both remittent and intermittent fever, on account of which he threw up his situation there, and went to the island of Madeira, where he met a Lancashire woman, and married her. They remained at Madeira eight months, and then went to Durban, Cape of Good Hope, the wife being eight months pregnant, and never having had any symptoms whatever of malaria. A week after her arrival Dr. Felkin saw her, complaining of a curious sensation in the abdomen, and he distinctly felt the fœtus shaking. The lady said the same thing had happened on several previous occasions, though never so markedly before. The phenomenon occurred at the same hour for four consecutive nights, when labor came on. Forceps were called for, and delivery was obstructed by the distended abdomen of the child caused by enlarged spleen. After birth the child had seven attacks of ague, characterized by the cold, hot and sweating stages. The paroxysm lasted seven hours in all, and the rectal temperature was 102°. The father stated that just before, and for the month following his marriage, he had had several very severe attacks of ague.

A possible objection to assigning the entire responsibility for this case to the father lies in the fact that, after removal to Durban, they were in a place where malaria might be contracted, though of course, the exemption of the woman from all symptoms, and her short stay, would make her a very improbable medium for transmitting the infection to the child; besides that she stated that similar though less extreme shakings of the fœtus had been observed by her before.

In the second case the child's parents had been married twelve years. The mother had never been away from Edinburgh. Three children had been born, all at full time, and quite healthy, during the first seven years after the parents' marriage. The father then went as fireman on a steamer trading with West African ports. The men were forbidden to land at the ports, but the second engineer and this fireman managed to escape several times, and had severe remittent fever. The engineer died, and his death so frightened the fireman that he did not go on shore again, although he remained another year in the service, suffering from ordinary ague. He had never suffered from syphilis. Ten months after his return home a child was born at full time, but it soon "pined away and died." Rather more than a year

later another child was born, which was always ailing, and had a rather enlarged spleen, but was greatly improved by appropriate treatment.

In the last and sixth pregnancy Dr. Felkin observed an attack of pain and fluttering "like a bad quickening," which lasted an hour, and recurred twenty-four hours, and again forty-eight hours later. The woman described it as like attacks she had had with her two previous children. Labor came on after one of these attacks, and the child was born at seven and one-half months. After birth it had two attacks of ague, at intervals of twenty-four and forty-eight hours respectively, and died in the cold stage of the second. In the first attack after birth the cold stage was very well-marked, the child distinctly shivering, and continuing to do so for rather more than half an hour. The hot stage lasted about two hours, and was followed by fairly profuse perspiration, the cotton-wool in which the child was wrapped becoming quite wet. During the attack the temperature was taken several times, and the highest point reached was 102.6°. The post-mortem appearances were fairly confirmatory of the clinical diagnosis of malaria.

If these cases be substantiated by other similar ones, they will go to place malaria beside syphilis as one of the diseases which can be transmitted directly from the father to the child, without the necessary infection of the mother; and if the plasmodium malariæ can gain access to the spermatozoon, may not, after all, the bacillus?

INTESTINAL TROUBLES OF INFANCY.

DR. L. G. BROUGHTON, of Reidsville, N. C., writes to the *North Carolina Medical Journal* on the above subject. As the result of quite an extensive country practice, he has met with only three grand divisions of infantile diarrhœa — simple diarrhœa, cholera infantum, and dysentery. He is satisfied that, in the vast majority of cases, decomposition in the gastro-intestinal tract is the *fons et origo mali*. And he finds these three great indications predominant; first, to clear out the bowels; second, to arrest decomposition and putrefaction; third, to restore healthy action in the alimentary tract.

To meet the first indication there is nothing better than castor oil, provided the stomach can bear it. With many practitioners rhubarb, either in powder in syrup or infusion, answers well in cases where castor oil is objectionable. To meet the second indication he uses salicylate of soda. To a child of from six months to two years old he would give three grains every two or three hours. This, he thinks, may be advantageously combined with pepsin, two or three grains. Another antiseptic of which he speaks in high terms is the sulpho-carbolate of zinc, in the dose of one-sixth to two grains. The third indication is fulfilled by suitable nutrients, as pancreatized milk, scraped raw beef, and tonics, as per-nitrate of iron and columba.

Dr. Victor C. Vaughan, in a late number of the *Dietetic Gazette*, speaks of the requirements necessary in the preparation of food for infants in the intestinal troubles of summer. (1) Cow's milk used as food for infants, should be sterilized. This is best effected by boiling. (2) The proteids in cow's milk may be made to more closely approximate those of woman's milk by partial digestion, at least by conversion into the soluble form. All chemists are agreed that the proteids of woman's milk are more easily digested than the same food stuffs in cow's milk. Dr. Vaughan would, therefore, counsel the partial artificial digestion of cow's milk, when used as food for infants, especially for those of weak digestive organs. On the other hand, he is convinced that this digestion should not be complete. In the first place, the digestive organs would be greatly weakened if the food used for any great length of time should be completely digested before its administration. Moreover, the use of wholly digested proteids in quantity is not free from danger, as experiments have shown that if peptones be directly injected into the blood they are poisonous. Normally it is a function of the liver to arrest and alter the products of proteid digestion in the stomach and intestines; but if a great quantity of ready-made peptones be poured into the stomach, they will be absorbed so rapidly that the liver may fail to perform this function fully.

The deficiency of carbo-hydrates in cow's milk may be supplied by the addition of milk-sugar or dextrin. Milk-sugar is too expensive to be used on a large scale. Common sugar acts as an intestinal irritant, and causes diarrhœa. Starch is not digested by the young child. Dextrine is easily prepared, is not acted upon by the yeast ferment, but is converted by diastase and by the pancreatic juice into maltose.

MEDICAL NOTES.

— A physician of Philadelphia insisted upon driving a fractious horse, and thus disregarded the suggestions of his coachman. The horse ran away, the coachman was thrown out of the carriage, his skull was fractured, and one of his legs was twice broken. Now the coachman sues the doctor, putting his damage at $10,000.

— The subject for a prize competition of essays has just been announced by the Dutch Scientific Society in Harlem. It is a "Critical review and exhaustive description of the different kinds of bacteria contained in drinking water before and after its filtration through sand, and of the methods of determining the characteristics of every kind." The successful competitor will receive a gold medallion or 150 Dutch gulden. The judges will award an extra prize of 150 Dutch gulden if they consider the successful competitor worthy of it. All competitive essays must be filed with the Society's secretary before January 1, 1890, and must be written in the French, Dutch or German language.

BOSTON AND NEW ENGLAND.

— The annual festival in aid of the Carney Hospital will be held in Music and Bumstead Halls, the last Thursday of October next.

— A case is reported from one of the suburbs of Boston, in which a young man suffering from typhoid fever, in his delirium shot and killed his nurse, a woman fifty years of age, and tried to shoot one of his relatives as well. A revolver had, it seems, been left where he could get at it. In the present season of typhoid prevalence too great care cannot be taken to watch with unceasing vigilance patients who are, or are liable to become, delirious from this cause, and to keep them away from any opportunities of doing harm, in a sudden frenzy, to themselves and others.

Miscellany.

AN EXTRA-UTERINE PREGNANCY DATING THIRTY-THREE YEARS.

M. TARNIER presented recently before the *Académie de Médecine*, says the Paris correspondent of the *Medical Press*, a woman, who had an extra-uterine pregnancy since 1856. This pregnancy arrived at the full period, the beating of the fœtal heart being plainly felt. The accoucheur having diagnosed the exact condition of the case, asked the advice of the late Paul Dubois as to a prompt intervention. The latter did not approve of an operation, counselling to leave matters as they were. At the end of a few days the fœtal heart seemed to have stopped, and the pains became much less intense, and finally disappeared completely. The woman returned to her usual duties. In 1859 she consulted the renowned surgeon, Nélaton, but he also refused to interfere. Her present condition is as follows: Beneath the umbilicus an extremely hard tumor is felt divided into two parts, one representing the head, the other the feet of the fœtus. To the touch it is not painful, and the woman seems not to suffer any inconvenience from its presence.

THE INSPECTION OF THERMOMETERS.

AT the thermometric bureau of the Yale College Observatory, during the last year, the comparison of thermometers has continued to be made by Mr. C. B. Peck, says *Science*. The number received for verification during the year ending June 1, 1889, was 7,475, being 249 in excess of the preceding, the maximum year. It is perhaps well to call public attention to the fact, not new, but continually overlooked, that the most accurate thermometers may be made to give false testimony by misinterpretation of their language. Although every certificate issued from this observatory, for other than clinical thermometers, contains a statement of the only conditions under which the correction therein given can be truthfully applied, they are continually called upon to explain, especially in the case of high-temperature thermometers, that, when only the bulb is immersed in a liquid of high temperature, the indicated temperature is too low by an amount depending upon the number of degrees of the mercury in the cooler stem and the difference between the temperatures of the bulb and stem. They have been called upon to show frequently that this error, which is independent of any correction due to the thermometer, may be as much as eight or nine degrees in the case of high temperature oils, as their temperatures are generally measured. A simple remedy for this indefiniteness of measurement would seem to be a special form of thermometer, in which nearly all the mercury should be immersed. Of the same nature is the correction of possibly 0.1° to be applied to clinical thermometers of the "Indestructible Index" form, when the detached column of mercury constituting the index is quite long (expressed in degrees), and is read after removal to a much cooler atmosphere; but the probable error on this account does not exceed the probable error of reading.

CHINESE OBSTETRIC CUSTOMS AND SUPERSTITIONS.

DR. A. M. FIELDE writes interestingly on facts and superstitions concerning pregnancy and parturition as observed at Swatow, China, in the *Philadelphia Medical News* for August 24th.

Nearly all the Chinese women maintain a sitting posture during labor and delivery. A few are unable thus to bring forth the child, and these are called "recliners."

The umbilical cord is never divided until after the emergence of the placenta, because it is supposed that this would cause the contents of the womb to rise and remain among the internal organs, causing speedy death. After the appearance of the placenta, the cord is tied by a thread, about one inch from the umbilicus; a loop is made by bringing the distal portion toward the body; a second knot is tied securely upon the first over the double cord, "to prevent the entrance of wind," and the cord is then cut near the second knot. The part of the cord left with the placenta is not tied.

If there is much delay in the expulsion of the secundines, various methods are pursued in assisting the patient. The mother-in-law or midwife goes behind the house in which the patient lies, raps smartly with a carrying-pole on the wall, and shouts, "Is it out yet?" An assistant responds from inside the house, "It is out." This performance is repeated, with short intervals, until the desired result is effected.

Another method of hastening the expulsion of the afterbirth is to have the patient lean over a horizontal bar, supporting herself partially upon her hands. This sometimes starts the adherent placenta, but is discomforting to the attached infant.

Some midwives insert the hand and detach the placenta, but mothers greatly fear this operation. It is asserted that one woman had her liver pulled out by the attending midwife, and consequently died. Native male physicians are under no circumstances called in cases of childbirth.

A girl that is born face downward, or one that is guilty of micturition or defecation immediately after birth, is straightway smothered, because of a superstition that such a child would be injurious to its parents.

A pregnant woman is advised not to handle edged tools. If she does so, her offspring is likely to lack a finger or a toe, or to have a harelip or a split ear.

Two pregnant women will not sit together on the same bench. As each woman hopes that her child is a male, and as it is thought that there may be an occult exchange of sexes between embryos that are brought into vicinage, it is considered wise to avoid the risk of having the supposed masculine tenant of the womb superseded by a female.

If a child has been touched by a pregnant woman, and sickens soon afterward, its mother winds a skein of silk made up of threads of five colors around a potato and roasts the potato in ashes. If the silk is burned during the process of roasting, it indicates that the ailment was not caused by the touch of the pregnant woman. But if the silk is not burned, as sometimes happens, then the mother of the injured child throws the potato over her house, and it is believed to produce a miscarriage in the woman who has caused the disease, while the sick child recovers.

Many men have purses made by women approaching confinement, hoping that the woman's plethoric condition will be mystically reproduced in the money-bag!

BLINDNESS IN ENGLAND.

THE number of the blind in the United Kingdom, according to the last census, was 32,296, says the *London Times*, being at the rate of 879 blind persons per million of the general population, as compared with 950 in 1871, 964 in 1861, and 1,021 in 1851. The decrease in blindness would thus appear to be gradual but steady, even allowing for the fact that many who have very defective sight and are practically blind object to return themselves as such. The number of those of school age in England and Wales, is 1,710, or one-thirteenth, a surprisingly small proportion, which points to the fact, well known to specialists, that blindness, as a rule, supervenes in later life, the average age of the blind being forty-nine. Their general condition has been much improved of late years, owing to the prevalance of more enlightened notions and the increase of special institutions. But the Commissioners remark that, in spite of the large charitable funds and philanthropic efforts devoted to their welfare, they feel convinced much may be done to better the condition of the blind and render them more independent of charitable aid than at present.

Accidents from flying pieces of stone or chips of metal are accountable for 58 per cent. of injuries to the eye, and in the case of 4 to 4½ per cent. of such accidents the sympathetic inflammation of the remaining eye, which so often sets in, leads to total blindness. Shuttle accidents, formerly very frequent, were diminished by the introduction of shuttle guards, and the number of cases at the Royal Eye Hospital, Manchester, decreased from twenty-one in 1884 to nine in 1885. Strong protective glasses of talc or mica or fine wire goggles are a valuable safeguard against such calamities, and early surgical treatment is of high importance. Granular ophthalmia in badly-ventilated and badly-lighted dwellings is another cause, but with proper sanitary precautions this is preventible, and during the recent occupation of Egypt no loss of sight from ophthalmia occurred among our troops, owing to the excellent care exercised by the medical staff.

One of the most fruitful causes of blindness is the inflammation of the eyes of newly-born infants, and the Ophthalmological Society estimated that 30 per cent. of the inmates of the institutions, and 7,000 persons in the United Kingdom, had lost their sight from that cause. Various specifics are mentioned by the Commissioners, but they all seem to depend chiefly for their success on prompt application.

THE TREATMENT OF LACERATION OF THE CERVIX BY THE OBSTETRICIAN.

IN the Obstetrical Section of the American Medical Association, at its recent meeting, Dr. Henry C. Coe read an important paper on the above subject, in which he remarked, as reported in the *American Journal of Obstetrics:*

It is common to hear patients abuse the accoucheur for lesions resulting from parturition, for the cure of which they are obliged to consult the gynecologist. The gynecologist himself is not always prompt to defend his *confrère*. Perhaps it is because in many instances he cannot conscientiously do so. It is not the purpose of this paper to enter into a discussion of the question of actually preventing serious lesions of the genital tract by proper attention during parturition. There is great difference of opinion as to the percentage of lacerated cervices in which the tear might have been prevented. Of course the prophylaxis can usually be observed only where the accoucheur himself performs some manipulation within the os. In such cases, as well as in rapid labors and occipito-posterior positions, we should be on the lookout for laceration of the cervix, and be ready to treat it when it occurs. The tendency of scientific obstetricians now is to leave the genital tract as far as possible alone after parturition, on the same principle that the surgeon relies upon his antiseptic details during the operation and does not disturb the dressing as long as there is no rise in temperature. We may go to the other extreme. The "antiseptic pad" of Garrigues has led to abuses in the way of non-interference where local examination and treatment were urgently indicated. In our anxiety to avoid "meddlesome midwifery" we may make too light of lesions that are really serious. The accoucheur should never, in his exultation at having successfully terminated a difficult case of labor, lose sight of the fact that while the patient may forget that he saved her life, she can never forget or forgive his making light of a laceration of the cervix or perineum for which she must undergo a subsequent operation. Whenever we have reason to suspect that a laceration of the cervix has occurred, we should look for it and treat the case accordingly. The treatment may be immediate or secondary.

(1) *Immediate.* — In a small number of cases (version or instrumental delivery) the cervix is so deeply torn that the hæmorrhage from the circular artery is sufficiently dangerous to threaten. Here prompt action is necessary. One or two deep wire sutures should be introduced. The practice of introducing tampons, giving astringent injections, etc., under these circumstances is to be condemned. Follow the ordinary surgical rule — to ligate the severed artery.

(2) *Secondary (or subsequent) Treatment.* — Do not attempt to repair the laceration by sutures, either at the time the laceration occurs or during the puerperal month. Wait until involution has proceeded — at least three months. Rely on perfect cleanliness, anti-

septic vaginal injections, and iodoform suppositories. Local applications to the torn cervix during the puerperal month are reprehensible. Keep the patient in bed longer than usual. Be on the watch for septic infection, especially the insidious form of parametritis. When the patient goes about, support the uterus with a pessary if it remains large and tends to sag downward.

As a result of this treatment, many cases of extensive lacerations of the cervix heal during the puerperium. References to author's experience in private and hospital practice and Dr. Emmet's views confirmed this.

Conclusion. — We are still far from realizing the scope of preventive medicine. No reason why such a large proportion of female ills should originate from what we denominate a "physiological process." Nature is kind, but we sometimes trust her too much. It should be the aim of the obstetrician to forestall the gynecologist. Allusion has been made to only one puerperal lesion, but how many more serious troubles (salpingitis and oöphoritis) might be avoided by greater care of the woman during and after labor? The subject is not a new one, and the author merely seeks to reawaken interest in it. The general practitioner should feel his responsibility more. It should be his aim to look beyond immediate results to those more remote. His present triumphs should not be bought at the expense of future and well-merited blame.

Correspondence.

[From our Special Correspondent.]

PARIS LETTER.

PARIS, August 16, 1889.

MR. EDITOR, — That most important question anent the marriage of syphilitic subjects has been very ably treated of by Dr. Langlebert, Jr., the well-known syphilographer. He is far from the opinion of some medical men, who would interdict the marriage of all syphilitic subjects. Supported by the statistics of Diday and the long experience of his father, who is also a well-known syphilographer, he proposes certain rules by which, if acted upon, a syphilitic subject may marry without any fear of seeing his progeniture suffer from his antecedents. It is, of course, understood that the patient should not be the subject of contagious accidents. If he is affected with tertiary accidents, and consequently non-contagious, these accidents should not result in any persistent organic decay. A certain time should be allowed to elapse from the commencement of syphilis and the appearance of the last specific accidents. According to the statistical researches of Diday, for severe syphilis, the longest period that elapsed between two successive eruptions, was one hundred and thirty-two days. Dr. Langlebert admits that a person who, having had a slight attack of syphilis, properly treated during fifteen or eighteen months, and passed one year without being affected, may be considered cured. However, he would still recommend, as a test, another year; and when the marriage is decided upon, he would exact that the patient be again submitted, *ante nuptias*, to a specific treatment of two or three months. These rules appear simple enough, but some medical men affirm that syphilitic subjects may have fresh accidents after a more considerable time.

To this, Dr. Langlebert replies, that these accidents are not contagious, and consequently cannot be transmitted to the wife. Moreover, in a note previously published, the author admits that the father cannot himself alone transmit syphilis to his children; the children have nothing if the mother had not been previously infected. It is much more rare that a syphilitic woman desires to contract marriage. In this case, Dr. Langlebert admits that the absolute interdiction should be the rule.

In connection with this subject, I may here give the summary of a clinical lecture recently delivered by Dr. Mauriac, at the Hôpital du Midi, a hospital for venereal affections in the male sex. To the question, whether a man once affected with syphilis can marry without any risk of infecting his wife, Dr. Mauriac replies, that it is prudent to wait a more or less long time; and he does not think, that, as a general rule, a syphilitic man should be condemned never to marry. He should, however, be advised not to marry before the third year which follows the appearance of the primary chancre, or, at any rate, never before the completion of two years, and then only on the condition that the patient had been submitted to the usual anti-syphilitic treatment. The interdiction should be absolute when the chancre has assumed a phagedenic character, or when the organism is considerably damaged by the disease. In these conditions marriage should be postponed until cure, or the disappearance of the accidents should take place. When the chancre is of a mild type, when there are only slight secondary lesions which yield to the influence of treatment, the patient may, without danger, contract marriage eighteen months or two years after. As regards the treatment of syphilis, Dr. Langlebert, with his father, thinks that mercury is *the* specific which is certain and infallible against the accidents of the secondary period, but he recommends that this medicament should be given only during the existence of the eruptions, and always in small doses. He even attributes to a chronic mercurial intoxication a certain number of accidents which other medical men attribute to cerebral syphilis, — cephalic, tremors, contractures, clonic convulsions, epilepsy, hemiplegia, locomotor ataxia (in certain cases), and particularly in intellectual disorders. The author is far from adopting the extreme hydrargyrism of Professor Fournier. He preferably recommends the administration of mercury by the stomach, frictions and subcutaneous injections being reserved for certain grave accidents, ocular or cerebral, against which the rapidity of the therapeutic action is the only condition of success. The duration and the resumption of the mercurial treatment will be measured by the duration and the returns of the secondary accidents of syphilis. Corrosive sublimate should be preferred to the protiodide of mercury. It should be given preferably in small doses, as it then acts as a tonic and reconstituent; in large doses, it is debilitating and dangerous for the nervous centres. The iodide of potassium is, on the contrary, the veritable specific for the more chronic stages of syphilis. It is advisable to commence its use about the fifth or sixth month. The average dose should be from one gramme to one gramme and fifty centigrammes per day. This iodide medication should be continued for about eighteen months, with periods of rest sensibly equal to the periods of treatment. At the end of these eighteen months the treatment of syphilis may be considered as completed, although it may still be prudent to resume the iodide of potassium for two or three months in the three consecutive years.

At a recent meeting of the Academy of Medicine, Dr. Dumontpallier read a note on a new treatment of endometritis, by the introduction, into the uterine cavity, of sticks of the chloride of zinc which are rendered supple, so that when once in the cavity, they become bent in all directions. But before the introduction of these sticks, the vagina is washed out with a solution of carbolic acid, of one per cent.; then the hysterometer, previously rendered aseptic, is introduced into the uterine cavity, to ascertain the direction of the latter. These sticks are left in the uterus; then after washing out the vagina, a plug is introduced, but the latter is not indispensable. In general, the slough produced by the caustic is expelled in about five days after its application. Vaginal antisepsy is strictly carried out, and the cure is effected two days after the escape of the slough. There has never been any narrowing of the uter-

ine cavity, and menstruation was soon restored. The author considers this method very inoffensive; for out of one hundred cases, there were ninety-six cures without complications, and four cures after complications due to imprudence committed by the patients. A certain degree of pain was caused by the caustic, but this soon became tolerable; but in many cases there was no pain. The general phenomena were *nil*, and there was no fever. From twenty-four to thirty-six hours after the cauterization a slightly rose-tinted discharge is observed, which precedes the escape of the slough. The vagina is then washed out with the liquor of Van Swieten.

DR. A. RICHET.

This gentleman is Professor of Clinical Surgery at the Hôtel Dieu; but he is now only nominally attached to this post, as for the last three years he has lived retired in his country house near Toulon, and has been replaced by *agrégés* of the faculty. This year he has been replaced by Dr. Kirmisson, a very distinguished surgeon. Dr. Richet was considered a very good surgeon of his time. He is now almost an octogenarian, and his doctrines are regarded as out of date. It must, however, not be forgotten that, about thirty years ago, Professor Richet was looked upon as one of the leaders in French surgery. His "Practical Treatise of Surgical Anatomy" opened out a new line, rendered the most eminent services, and obtained for the author a European reputation. This work, or as he proudly termed it, "The Book," is almost obsolete, as its contents are not altogether in keeping with the progress of the day. It will, nevertheless, be a lasting memorial to his fame. Notwithstanding his age, he had a certain amount of vigor, both mental and physical; but since the death of his wife, which took place about three years ago, under most painful circumstances, he gradually broke down and felt that he could no longer continue the active functions of his office. Before retiring, however, he has had the satisfaction of seeing his son, Dr. Charles Richet, grow to manhood, become successively Doctor and *Agrégé* of the Faculty of Medicine, and now become his colleague, as he is Professor of Physiology at the Faculty of Paris, which post he fills with great talent and honor.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 17, 1889.

Cities.	Estimated Population for 1889.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2810: under five years of age 1382; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas, and fevers) 862, consumption 596, acute lung diseases 137, diarrhœal diseases 596, diphtheria and croup 90, typhoid fever 87, whooping-cough 33, scarlet fever 19, malarial fever 18, cerebro-spinal meningitis 12, measles 4, erysipelas 2, typhus fever 1. From whooping-cough, New York 12, Chicago and Boston 5 each, Philadelphia and Springfield 2 each, Baltimore, St. Louis, Washington, Haverhill, Gloucester, Newton and Malden, 1 each. From scarlet fever, Chicago 6, Philadelphia and St. Louis 4 each, Baltimore and Washington 2 each, Lowell 1. From malarial fever, New York 6, Baltimore, New Orleans, and Charleston 4 each. From cerebro-spinal meningitis, Chicago 6, New York 3, Washington 2, Philadelphia 1. From measles, Chicago 3, New York 1. From erysipelas, New York and Chicago 1 each. From typhus fever, Philadelphia 1.

In the 28 greater towns of England and Wales, with an estimated population of 9,555,406, for the week ending August 3d, the death-rate was 21.0. Deaths reported 3763: infants under one year of age 1361; acute diseases of the respiratory organs (London) 182, diarrhœa 578, measles 79, whooping-cough 69, diphtheria 65, scarlet fever 59, fever 41.

The death-rates ranged from 14.1 in Brighton to 42.6 in Preston; Birmingham 23.1; Bradford 20.9; Hull 21.8; Leeds 23.2; Leicester 21.5; Liverpool 23.4; London 18.4; Manchester 27.0; Nottingham 19.7; Sheffield 20.7; Sunderland 28.8.

In Edinburgh 17.2; Glasgow 20.5; Dublin 20.7.

The meteorological record for the week ending Aug. 17, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending Saturday, Aug. 17, 1889.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.		Velocity of Wind.		State of Weather.[1]		Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 19, 1889, TO AUGUST 23, 1889.

Leave of absence for one month is granted Lieutenant Colonel JOSEPH C. BAILY, surgeon U. S. A.; Medical Director, Headquarters Department of Texas, San Antonio, Texas, August 17, 1889. S. O., 54, Headquarters Department of Texas.

Commanding officer at Jackson Barracks, Fla., telegraphs the adjutant general of the army, that Major Harney E. Brown, surgeon U. S. A., died at Jackson Barracks, August 20, 1889, at 1.40 o'clock, P. M.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING AUGUST 24, 1889.

W. K. SCOFIELD, medical inspector. Detached from the "Lancaster."

C. T. HIBBETT, past assistant surgeon. Detached from the "Lancaster."

C. H. WHITE, medical inspector. Ordered to "Pensacola."

F. A. HESLER, past assistant surgeon. Ordered to "Pensacola."

L. W. CURTIS, past assistant surgeon. Ordered to the "New Hampshire."

W. H. JONES, surgeon. Detached from the "Pensacola." Placed on waiting orders.

L. VON WEDEKIND, assistant surgeon. Detached from the "New Hampshire" and ordered to the "Pensacola."

DEATH.

In Longmeadow, Mass., August 20th, Thomas L. Chapman, M.D., M.M.S.S.

SOCIETY NOTICES.

AMERICAN DERMATOLOGICAL ASSOCIATION. — Programme of the Thirteenth Annual Meeting, to be held at 19 Boylston Place, Boston, Mass., September 17, 18 and 19, 1889.

First Day. — Morning Session at 10.30, A. M. Papers: Address by the President, Dr. J. E. Graham; (1) Clinical Notes on Herpes Zoster, Dr. F. B. Greenough; (2) Microscopical Studies of Malignant Tumors of the Skin, Dr. C. Heitzmann; (3) Clinical Observations on Injections of Insoluble Mercurial Salts in Syphilis, Dr. H. G. Klotz. Afternoon Session at 3.30, P M. Papers: (4) Contribution to Dermatological Bibliography, Dr. G. T. Jackson; (5) Clinical Notes on Sycosis Capillitii, Dr. J. Zeisler; (6) Two Cases of Eczema Mercuriale, Dr. J. F. Shepherd; (7) A Case of Urticaria Pigmentosa, Dr. H. W. Stelwagon.

Second Day. — Morning Session at 10.30, A. M. Report of Committee on Statistics. Report of Committee on Nomenclature. Papers: (8) A hitherto undescribed form of New Growth of the Vulva, Dr. R. W. Taylor; (9) Observations on a disputed point in Infantile Eczema — Some general suggestions in Dermatological Therapy, Dr. S. Sherwell; (10) Additional Cases of Dermatitis Palmaris and Plantaris, Dr. L. D. Bulkley. Afternoon Session at 3.30, P. M. Papers: (11) Dermatitis Papillaris, Dr. C. Heitzmann; (12) On the Occurrence of Prurigo in America, Dr. J. Zeisler; (13) On the alleged tolerance of the Iodids in Syphilis, Dr. H. W. Stelwagon; (14) Relapse of Pemphigus Foliaceus after twelve years' quiescence — Case of Impetigo Herpetiformis, Dr. S. Sherwell.

Third Day. — Morning Session at 10, A. M. Demonstration of Cases. Retirement of Old and Induction of Newly Elected Officers.

All physicians are cordially invited to attend.

G. H. TILDEN, M.D., *Secretary.*

AMERICAN PÆDIATRIC SOCIETY. — Organized in Washington, D. C., September 18, 1888. Preliminary Programme.

The meetings will be held at the Army Museum Building, Washington, D. C., on the 20th and 21st of September, 1889. One of the afternoon meetings will be held in the Johns Hopkins Hospital, Baltimore, Md., by invitation of the Director of the Hospital.

Papers. — Address by the President. A. D. Blackador, Montreal: Notes on a case of Ataxia in a child of ten years. W. D. Booker, Baltimore: A study of some of the Bacteria found in the dejecta of infants afflicted with Summer Diarrhœa (second communication). Dillon Brown, New York: Noisy Respiration. A. Caillé, New York: Prolapsus Recti due to large stone in the bladder, in a girl three years old; Two cases of Nystagmus associated with choreatic movements of the head in rhachitic babies; Septic Diphtheria with unusual sequelæ; Personal Prophylaxis in diphtheria. Charles W. Earle, Chicago: Subcutaneous Emphysema in children; The necessity of prolonged rest after some attacks of Diphtheria; Two cases of Carpo-pedal Contraction. J. Henry Fruitnight, New York: The treatment of Scarlet Fever and its complications. Francis Huber, New York: Spurious Meningocele; Double Empyema. A. Jacobi, New York: Aneurism in early life. John A. Jeffries, Boston (by invitation): A contribution to the Summer Diarrhœas of Infancy. H. Koplik, New York: Tuberculosis of the Testis in childhood. Thomas S. SOME REMARKS ON TYPHOID FEVER, WITH AN ANALYSIS OF ONE HUNDRED AND TWENTY-NINE CASES TREATED IN HOSPITAL, AND SPECIAL REFERENCE TO RELAPSE.[1]

BY FREDERICK C. SHATTUCK, M.D.,
Professor of Clinical Medicine in Harvard University, Visiting Physician to the Massachusetts General Hospital, etc.

HAVING exchanged a summer for a spring service, and being consequently likely to have fewer cases of typhoid fever to treat in hospital, in coming than in past years, I determined to analyze, with reference to certain points, all the cases of this disease which entered my wards during my term of service in the years 1886, 1887 and 1888. The number of cases is not large enough to allow the deduction of any very general conclusions, and yet this analysis may be compared with those of others who deal with larger figures, may perhaps contribute in some small degree toward the structure of our complete knowledge of the subject, and has certainly proved interesting and instructive to me. The fact that the cases were nearly equally distributed between three successive years, diminishes somewhat the sources of error which may be connected with the study of the cases of a single year; and they were also under the care of the same person, in the same institution, and were treated on precisely the same general plan, — essentially the so-called expectant.

With very few exceptions the cases were in adults. Abortive cases have not been counted among the number, which includes only those to the diagnosis of which no reasonable doubt can attach. I find it difficult to understand how anybody who has studied the subject, and has had also a moderate experience, can deny that typhoid fever may abort, the intestinal lesions probably never reaching the stage of necrosis and ulceration. The characteristic lesions are not accessible to direct sight and touch in all cases, fatal and non-fatal alike, as they are in the more purely eruptive specific fevers, the existence of extremely mild and abortive cases of which is not questioned. There are, moreover, a sufficiency of house and local epidemics recorded in which some of the exposed individuals went through the fully developed disease, or died during its progress; while others, presenting prodromal and initial symptoms the same in kind, and of equal, less, or even greater severity, were apparently quite well again within a week, more or less. Indeed, it seems to me that there is absolute proof that typhoid fever may exist and even prove fatal, without the presence of fever at any time, with even sub-normal temperature throughout. Strube,[2] in a typhoid epidemic among the German troops besieging Paris, was struck by the low range of temperature which characterized the outbreak. He tells us that fourteen cases had a normal or subnormal temperature throughout. In one of these, the first rise was co-incident with suppuration about the rectum, which helped to carry the man off. At the autopsy, fully formed and typical typhoid lesions were found. In these cases all the usual symptoms, including even furious delirium, were present. Fraentzel,[3] in charge of another military hospital at the same time, was also struck by this peculiarity of the temperature. Again,[4] a soldier enters a hospital in India for eczema, is free from fever or other general symptoms, dies suddenly, and is found to present typhoid lesions on the autopsy table. These considerations are of importance in estimating the general mortality rate of the disease. Excluding, then, all abortive or otherwise doubtful cases, those cases are included which proved fatal within a few days of admission, the patients entering in a desperate condition.

I. The number of cases, by years, with the yearly and total mortality rate, is as follows:

TABLE I.

	1886.	%	1887.	%	1888.	%	Total.	%
Number of cases,	39		45		45		129	
Recovered,	35	89.7	42	93.33	41	91.2	118	91.63
Died,	4	10.3	3	6.67	4	8.8	11	8.37

A mortality rate of 8.37 % is not high, except as compared with the recent and large statistics of Brand and his followers. Hæmorrhage occurred in two of the fatal cases, but in only one of these it was sufficient in itself to excite alarm. Cheyne-Stokes respiration was noted in two; in a like number, broncho-pneumonia played an important part; in one, pericarditis was a complication; in one, general convulsions closed the scene after the fever had nearly run its course; one death took place during a relapse, the patient being fifty-four years of age; in four, deaths occurred within a week after entrance. In none of the fatal cases was unusually or continuously high fever a feature.

II. The state of the bowels, the occurrence of epistaxis, and the existence of splenic enlargement.

TABLE II.

	1886.	%	1887.	%	1888.	%	Total.	%
(a) *Bowels.*								
Diarrhœa,	11	28	6	13	15	33	32	25
Constipation.	17	44	14	31	16	35+	47	36
Alternating,	4	10	16	37	11	24+	31	24
Regular,	7	18	9	19	3	7	19	15
(b) *Epistaxis.*	18	46	14	31	16	35	48	38
(c) *Spleen.*								
Area of dulness,	26	67	27	57	16	35	68	53
Organ felt,	9	23	15	33	9	20	33	25.5

This table shows that in 51 % of all the cases there was no diarrhœa at any time; that in 36 % the bowels moved only after enemata, which, in these cases, I order every second day. In the cases included under the heading "alternating," looseness of the bowels was only a transitory feature; and in only 25 % was this symptom really prominent, a smaller percentage than what is said in the text-books would lead one to expect.

Splenic enlargement, I cannot help thinking, is not an absolutely constant accompaniment of typhoid. Of course there are cases in which a rigid or tense abdominal wall presents insuperable difficulties to satisfactory palpation; there are those in which tympanites completely masks the splenic dulness; while there are, again, others in which fæces in the descending colon may on one or two examinations give rise to a dulness simulating that due to splenic tumor. But I feel sure that I have watched a fair number of cases in which I should have been able to feel the organ if enlarged, and failed to do so in repeated examinations. Indeed, I never feel sure of enlargement unless I can feel the organ descend on deep inspiration.

[2] Berliner Klin. Wochen., 1871, p. 357.
[3] Zeitschrift der Klin. Med., Bd. II.
[4] Dublin Journal of Medical Sciences, July, 1887.

No analysis of the frequency of rose spots, delirium, or tenderness and gurgling in the right iliac fossa was made.

III. The frequency and character of the complications and sequelæ, other than relapse, is shown in

TABLE III.

Intestinal hæmorrhage	7	5.4%
Venous thrombosis (femoral)	9	7
Furunculosis	10	7.7
Otitis media	3	2.3
Parotid or submaxillary swelling (in no case suppuration)	4	3
Periostitis	2	
Lobar pneumonia	2	
Melancholia	1	
Hemiplegia (embolic, early)	1	
Neuritis	3	2.3

The above list calls for no special comment; perforation is conspicuous by its absence.

IV. The next table shows the frequency of relapse, the significance attached by me to which term will appear further on.

TABLE IV.

1886.	1887.	1888.	Total.
7 17.66%	8 17.77%	6 13.33%	21 16.28%

It is not an easy matter to ascertain the frequency with which relapse is encountered by leading writers on typhoid, owing to the lack of a uniform definition of the term. The Germans, as a rule, class under this head only those secondary attacks which are preceded by an interval of apyrexia of varying length; recrudescence denoting a secondary attack which begins before the complete defervescence of the primary attack. English writers, on the other hand, notably Pearson Irvine,[5] the author of the best monograph on the subject in our language, with which I am acquainted, uses "relapse" as denotative of the renewal of the complete typhoid process, irrespective of the time of its onset; while the term "recrudescence" is applied to the pyrexia, more or less transitory, attributable to a complication, sequela, or an error in diet. In other words, fever recrudesces; typhoid fever relapses. It seems to the writer that Irvine's definition is the better of the two; a relapse is a relapse, at whatever time it may begin, whether intercurrent or consecutive. It may be that in the former the fresh crop of bacilli starts from the intestinal tract directly; in the latter that the spleen or some other part has served as a sort of half-way house for the storage of potentially active bacilli which, again reaching the intestinal glands, reproduce their kind. This may be true, but is at present purely hypothesis.

Schmidt,[6] analyzing 561 cases, finds the percentage of relapse, in the English sense, to be 11.6 (intercurrent 4.8%); Ziemssen,[7] in 832 cases, finds consecutive relapse in 13%; Steinthal,[8] in 539 cases, in 7.5%. The event under consideration was, therefore, rather more frequent in my cases than in those of Schmidt, probably rather less so than in those of Ziemssen. By other authorities the frequency is set down as varying from 5 to 15 per cent. Ziemssen, following Gerhardt, thinks that relapse is to be expected if the splenic tumor does not subside with the subsidence of the fever of the primary attack. My experience has satisfied me of the truth of Irvine's observation, that a relapse may be so free from symptoms apart from the fever, which itself may be trifling, as to be entirely overlooked if temperature observations are omitted as soon as the primary fever ceases. It is, moreover, probable that a relapse may abort; may be of very short duration; may occur at such a period in the primary attack, may be overlain by a complication, or otherwise so obscured as to be extremely difficult, or even impossible, of recognition. In this analysis all doubtful cases have been thrown out.

Relapse occurred in twenty-one cases; in one of these it was repeated a second time; we have thus twenty-two secondary attacks for study.

(1) Intercurrent or consecutive.

In eleven the relapse began before complete defervescence, in eleven after; 50% in either case. By defervescence is implied the first normal evening temperature. This fact seems to me to show conclusively, if indeed the point needs any further demonstration, that we are now powerless to prevent relapse, and that errors in diet are in no way causative of it. In the great majority of my cases the relapse started without any change from the liquid, oftentimes exclusively milk, diet. This point seems to me worth insisting on, if for no other reason because the laity are still in the darkness with regard to it, which enshrouded us until comparatively recently. Constipation, nourishment unsuitable in kind or too large in amount, the excitement of a visit, or a number of other causes may produce a return or an exacerbation of fever; to produce a relapse there must be a re- or auto-infection.

(2) Interval.

In my eleven intercurrent relapses the renewal of the process took place from the third to the fifth week, but this is a point on which I do not lay much stress, as it is proverbially difficult, especially in hospital cases, to fix the onset of the disease. The apyrexial interval which separated the primary from the secondary attacks, in the eleven cases of consecutive relapse, is shown in the following table:

TABLE V.

1 day in 2 cases.	6 days in 1 case.
2 days in 4 cases.	8 days in 2 cases.
3 days in 1 case.	9 days in 1 case.

Of course there is a slight liability to error in fixing the date of onset, but it is very much less than obtains with the primary attack.

(3) Duration.

Of the twenty-one recoveries, — one patient, fifty-four years old, died on the eighth day of a relapse, — the duration of the secondary attack was as follows.

TABLE VI.

11 days in 1 case.	21 days in 3 cases.
14 days in 1 case.	23 days in 1 case.
15 days in 2 cases.	24 days in 1 case.
16 days in 4 cases.	26 days in 1 case.
17 days in 3 cases.	27 days in 1 case.
19 days in 1 case.	29 days in 1 case.
20 days in 1 case.	

This gives an average of nineteen days, a period somewhat shorter than that belonging to primary attacks. This average duration corresponds closely with that which Irvine believes to represent the truth. Ziemssen and other German writers speak of relapses lasting four, five or six days, and their average duration is thus brought down to eleven to fourteen days. If abortive primary attacks take place there is cer-

[5] Relapse of Typhoid Fever, London, 1880.
[6] Deutsches Archiv. f. Klin. Med., 1888, Bd. 43, p. 127.
[7] Ibid., 1884 Bd. 34 p. 375.
[8] Ibid., Bd. 34, p. 357.

tainly no reason why secondary attacks should not also abort. I believe that they may, but have excluded cases which might have been classed here, because I believe the clinical distinction between such very short relapses and some obscure complication, to be a difficult one, and my records are not as complete with reference to outbreaks of fresh rose spots and persistence or renewal of splenic tumor, as I could wish. The temperature curve alone may be sufficient for the diagnosis of a fully developed relapse; but other points must, it seems to me, be taken into account to establish the presence of an abortive relapse. The single death, a mortality of less than 5%, was in a consecutive attack. My limited experience does not bear out the German view that the intercurrent are much more severe and dangerous than the consecutive attacks. Ziemssen's mortality rate for the former is 15.5%, for the latter, 2.8%.

(4) Temperative curve.

This, according to Irvine, has in relapse two marked peculiarities: first, the maximum is reached with a striking, though not absolute, constancy on the fifth day; second, there is apt to be a decided fall on the eighth or ninth day, with a quick subsequent rise of some days' duration, before true lysis begins. An analysis of my cases, with reference to the first of these points, appears in

TABLE VII.

Maximum reached on fourth day in 5 cases.	
Maximum reached on fifth day in 8 cases.	
Maximum reached on sixth day in 5 cases.	
Maximum reached on seventh day in 3 cases.	
Maximum reached on eighth day in 1 case.	

Thus in eighteen of twenty-two cases the fever reached its height on the fourth to the sixth day, and more often on the fifth than on any other one day.

With reference to the second point, my results do not correspond so closely to those of Irvine. In only six of my cases did the drop occur on either the eighth or ninth day; in some cases on the sixth; in more on the tenth or eleventh; in others no marked drop took place, but the fever terminated by an uninterrupted but gradual lysis.

Treatment. — As has been before indicated the treatment in the above cases was essentially expectant. In 30% no drug of any kind and no alcoholic stimulant was given at any time in the duration of the disease.

TABLE VIII.

	1886.	%	1887.	%	1888.	%	Total.	%
No medicine or stimulants,	9	23	14	31	15	33	38	29
Medicines, stimulants, or both,	30	77	31	69	30	67	91	71

Thus it will be seen that 29% of all the cases received neither drugs nor alcohol at any period of the disease. When it is too late to supply the deficiency I find that the analysis for the three years is not as complete as I could wish, with reference to the proportion of cases in which simulants alone, drugs alone, or the two in combination, were given. In 1888 33% had neither, 31% stimulants only, 35% both. The drugs most used were digitalis and cocaine for cardiac weakness —with the apparently prompt and marked effect of the latter in some cases I was much pleased; an opiate and the bromides for restlessness and insomnia; an astringent for excessive diarrhœa. In seven cases I gave a preliminary ten grains of calomel on entrance, followed by naphthalene, eighty grains daily, to see whether intestinal antisepsis could be secured; the disease aborted, or its course shortened. The number of cases is small, but the results were not such as to lead me to persevere. In two cases strangury resulted; and in one of these, hæmaturia. Two young men were admitted almost on the same day, with histories and symptoms clearly indicative of typhoid: one received the calomel and naphthalene, the other, owing to a misunderstanding, did not; both with equal promptitude aborted. My friend, Dr. G. L. Peabody, of New York, whose suggestion it was which led me to try this plan, tells me that his later experience has not justified the hope which his earlier experience encouraged. It has occurred to me that perhaps we can apply the principal of intestinal antisepsis with better results to the prevention of relapse, giving β. naphthol or some similar remedy, more or less of which passes unchanged through the canal. I propose to try this, and hope that some one with larger facilities than I am now likely to enjoy, may be willing to do the same.

The internal antipyretics I used a good deal in 1886, in primary attacks; scarcely at all in 1887 and 1888, only on the rarest occasions in relapses. I now give them only in the comparatively rare cases in which the fever in itself seems to interfere with the comfort of the patient. While we believed the continued range of such temperatures as we ordinarily encounter in typhoid to be productive of the nervous symptoms, as well as of the granular degeneration of the parenchymatous organs, particularly the heart, it seemed rational to adopt measures of one kind or another, the effect of which is to keep the temperature constantly within relatively safe limits. The knowledge which we have now, limited as it is, with regard to the formation and effects of the alkaloidal poisons produced in the living body, renders it, to say the least, highly probable that, in the influence of these compounds on the nervous centres, lies the cause of most of the grave symptoms and of the chief fatality of typhoid and some other processes. Whether we err here or not, that pyrexia is not the evil spirit we thought it to be, seems to be clearly shown, for instance, by Gläser's[9] analysis of 200 fatal cases of typhoid, out of 3000 treated in the Hamburg General Hospital. In only 8% of the fatal cases was the average temperature higher than that of the ordinary mild type of disease; and in none of the fatal cases were higher points reached than we all see in cases which terminate favorably. He shows, too, that in these Hamburg cases the duration of the fever was as innocent of the fatal result as its height. Here I can refer again to the reports of Strube and Fraentzel. The low temperatures which marked their cases has been already alluded to; but the following facts are also noteworthy: the symptoms in many were extremely severe, but these cases were, as a rule, of short duration, ending either in death or convalescence within two weeks. Fraentzel's mortality was 39% of 41 cases; Strube's was less, but reached 14.1% in the cases with a temperature of less than 102.2° F. while it was only 8.5% in those of higher range.

Brand and his followers, the most strenuous advocates of a method of treatment one effect of which is temperature reduction, while they bring ever stronger proofs of the beneficial effects of cold bathing, do not

[9] Deutsche Archiv. für Klin. Med. 1887, Bd. 41, p. 1.

now attribute these effects to the temperature reduction as much as to the stimulation of the nervous centres and the deeper respiration which tends to prevent pulmonary complications. Brand[10] says that the difference between his method and the antipyretic is that his is directed against the process as a whole, while the other is only against a symptom. "The process causes the danger, not the temperature." And here I may add that the conclusion is forcing itself upon me that we must come to the cold water treatment in this country. Expense and trouble are not offsets to human life in the minds either of the profession or the public. One cannot read the writings of Brand, Juergensen, Ziemssen,[11] and others in Germany; of Bouveret[12] and other members of the Lyons school in France; or of such expositions of their results as have recently been printed in this country by Wilson,[13] Wood,[14] and Baruch,[15] without seriously questioning whether we are doing our whole duty by our typhoid patients. Contrast the following figures:

Boston City Hospital,	1879-1888,	1846 cases,	mortality	13.98%
Mass. General Hospital,	"	969 "	"	17
Brand, cold bathing fairly strict,		5573 "	"	3.9
" " very "		1223 "	"	1

Not one of the twelve fatal cases in the last series came under treatment before the fifth day. These figures do not require further comment here.

The treatment in my cases was purely expectant, except that spongings with alcohol and water at a temperature of 60 – 70 F. was practised every two, three, four, six, eight hours, according to the degree of fever, 102.5 being generally considered an indication for the application. My mortality, 8.3%, is certainly not high; but the number of cases is relatively small, and a few bad ones would have raised the mortality materially.

AN UNCOMPLICATED CASE OF PROGRESSIVE OPHTHALMOPLEGIA EXTERNA, OR A SYMMETRICAL PARALYSIS OF THE EXTERNAL OCULAR MUSCLES.[1]

BY FREDERICK E. CHENEY, M.D.,
Assistant Surgeon to the Massachusetts Charitable Eye and Ear Infirmary, Ophthalmic Assistant to the Out-Patient Department of the Massachusetts General Hospital.

THE patient, whose case I have to report, is a boy, thirteen years of age, of English parentage and birth. He first came to the Massachusetts Charitable Eye and Ear Infirmary, in March of the present year, during the service of Dr. Sprague. Ptosis was the only trouble complained of; and it was, in fact, the only defect of the eyes that had been noticed by himself or his friends. He was admitted as a house-patient a few days later, for operation, by which it was hoped to correct, in a measure, the faulty position of the lids.

The mother states that the eyes appeared perfectly natural at birth, and continued so until some time during his third year, when it was noticed that the upper lids drooped slightly over the fronts of the eyes. This drooping of the lids became more noticeable as the boy grew older, and continued to slowly increase until his ninth year, since when there has been no appreciable change.

There is no history of convulsions, headache, or injury, and with the exception of the usual diseases of childhood, he has always been well and strong. In view of the fact that a specific history is not unfrequently obtained in cases of this disease, it may be well to mention that the boy was vaccinated in his second year, and that soon after this quite an extensive eruption made its appearance. This soon disappeared, however, and was not accompanied or followed by other symptoms that would suggest specific inoculation. The family history is good: The mother has never had any miscarriages, and has given birth to four other children, three of whom are living, and are said to be perfectly healthy.

Examination. — The patient is found to be well-developed physically, and is bright and intelligent.

The ptosis is practically complete, on both sides — though the left is perhaps a little more marked than the right — and he is only able to separate the lids by bringing into action the occipito-frontalis muscle. By the action of this muscle, and by tilting the head backward, the lower half of the right and about one-third of the left pupil are exposed, so that he has little or no difficulty in seeing. On raising the lids the left eye is found to diverge slightly, and when he attempts to follow the movement of the hand with the eyes, symmetrical deficiency of motion is found in every direction; upward motion is almost entirely lost, downward is quite limited, and, although the inward and outward movements are fairly good, the borders of the cornea cannot be carried to either the outer or inner canthus, as they can when the internal and external recti muscles possess their normal form.

The pupils are moderately small, and react readily to light as well as to accommodation. He reads the finest print (Sn 0.5) at a distance of eight centimetres, which shows that there is no want of accommodation power. Diplopia is not complained of, but when questioned, he says that he sometimes sees double while looking at near objects. On raising the lids and asking him to look carefully at a white card at a distance of eighteen feet, I find that he sees it double, and it is made more noticeable when a colored glass is placed before one eye. Although there is some astigmatism, the sight is nearly up to the normal for distance, and is made quite so by the use of correcting glasses. Nothing abnormal is found in the transparent media, or fundus of either eye, and the fields of vision are not contracted in any direction, either for form or color.

Dr. Walton kindly made an examination of the boy's general muscular condition, and writes me as follows in regard to it: "I find no trace of muscular disturbance elsewhere; there is no fibrillary twitching, no atrophy, no weakness. His muscular system is everywhere unusually well-developed; the leg muscles being large, but not unnaturally so. All movements of head, trunk and extremities are normal. He gets up from the floor without using his hands. The tendon reflex is normal. The grasp by the dynamometer measures twenty in the left to sixteen in the right, to which I attribute no special importance."

Dr. Walton also suggests that iodide of potassium should be tried before operating. In accordance with which suggestion, beginning with five grains t. i. d., it

[1] Read, by invitation, before the Boston Society for Medical Improvement, May 27, 1889.

[15] N. Y. Medical Record, Feb. 16, 1889.

was rapidly increased to twenty grains t. i. d., and this was continued for a month without any noticeable change in the condition of the ocular muscles.

This case is undoubtedly one of uncomplicated, progressive ophthalmoplegia externa, and can be classed as one of the rarer forms of ocular paralysis.

The disease as first described by von Graefe in 1868, is characterized by a progressive, and as a rule, symmetrical paralysis of all the external ocular muscles; the upper lids drooping; the eye-balls becoming more and more limited in their movements, and in the end becoming almost completely motionless.

The intra-ocular muscles, in the uncomplicated form of the disease, do not suffer; the pupils retain their normal size and reaction, and the power of accommodation is unimpaired.

In 1879 Jonathan Hutchinson brought the disease into greater prominence by reporting seventeen cases; three of these were uncomplicated, while the remaining fourteen were complicated with other nervous diseases. Since the publication of Hutchinson's paper the affection has attracted a good deal of attention, and there has been quite a number of cases reported, both uncomplicated and complicated. I find but four of the uncomplicated cases reported in this country; two by Birdsall, one by Mittendorf, and one — a congenital case — by Tilley.

The disease, as a rule, occurs in otherwise perfectly healthy individuals. The atrophic changes remain confined to the ocular muscles; and as the accommodation and vision are not interfered with, the only inconvenience the patient is apt to suffer is from the immobility of the eyes, which, of course, necessitates more frequent movement of the head, and in some cases from the high degree of ptosis which compels him to tilt the head backward, so that the pupils may be brought below the borders of the drooping lids.

A few cases have been reported in which other nervous lesions, chronic bulbar paralysis, locomotor ataxia, and progressive muscular atrophy, developed in the course of this disease; but it is certainly not usual for other muscles to become involved when the atrophic changes begin in the ocular muscles. Although the pathology of this disease has not definitely been determined by autopsy, it is considered by Förster, Mouthner, and other investigators, to be a degenerative process involving the motor nuclei of the ocular muscles, situated upon the floor of the fourth ventricle and aqueduct of Sylvius, and is thought to be identical with the change occurring in progressive bulbar paralysis, and the spinal form of progressive muscular atrophy.

The centres of the motor oculi nerves are, as a rule, the first to become affected, and the corresponding muscles of the two eyes, supplied by these nerves, are usually involved at about the same time and in an equal degree. Exceptions to this symmetrical failure of power are rarely observed. Mouthner, however, reports one case, in which the ptosis developed in the left eye twenty years before it made its appearance in the right, and neither were the other muscles of the eyes symmetrically affected. At the time of Mouthner's examination some of the muscles still retained their normal power.

The levator muscles of the lids, in the majority of cases, never entirely lose their power, even when the other muscles supplied by the third nerves are completely paralyzed.

The degree of ptosis is therefore variable; it being sometimes so slight that it is not noticed by the patient, and causes him no inconvenience. It is usually, however, of a moderate degree, and is sometimes complete.

Diplopia is not often present, but it is sometimes complained of where the disease progresses with moderate rapidity, that is in cases where the loss of power becomes almost complete within a few months. In the larger proportion of the cases recorded the progress is very slow, and diplopia is not mentioned as being present. The case which I have just reported seems to be exceptional in this respect, as, although double vision is not complained of, it is found to exist, and is made more noticeable when the pupils are completely exposed by raising the lids.

In regard to the sex and age of persons afflicted with this disease, it is much oftener met with in males than females, and in most of the cases reported, the trouble has come on before the thirtieth year. I find the reports of three congenital cases, and of three others, including the case just mentioned, in which the trouble was first noticed during the third year.

Lawford reports one case, in which the lids began to droop when the patient was about fifty years old, and I do not find any others recorded where the trouble began later than this.

In regard to cause: a history of previous syphilis is sometimes obtained, though not as frequently in these uncomplicated cases as in the cases seen in connection with other nervous diseases.

The trouble is also sometimes dated from an injury. In Lawford's case, there is a possibility that the disease was hereditary, as the patient's grandmother and two male cousins are said to have drooping lids.

The prognosis, as far as any marked improvement in the ocular condition is concerned, is not good. A moderate increase in the movement of the eyes is sometimes observed, after iodide of potassium has been taken in large doses for a month or more, and there may also be some improvement in the ptosis.

Mouthner reports one case, a child eleven years old, that entirely recovered in two months, with no treatment whatever. The trouble developed rapidly in this patient; there being a complete double ptosis, three months after the first symptoms were noticed; there was also a slight facial paralysis, so that it can hardly be classed as a typical case of this disease.

ARSENIC IN THE COURTS.[1]

BY F. A. HARRIS, M.D.,
Medical Examiner for Suffolk County.

INASMUCH as arsenic is one of the best known of the deadly poisons, and as it is also one of the most easily obtained, owing to its extensive domestic use in the form of what is popularly known as "Rough on Rats," and its more extensive use in agriculture in the form of Paris green, it is not strange that by far the largest number of suicides by poison should owe their success to the ingestion of this particular one.

As white arsenic and Fowler's solution are practically free from taste or odor, and are readily administered in food or drink without liability to attract the attention of the victim at the time, it is not surprising

[1] Read by title before the Massachusetts Medico-Legal Society, October 3, 1888.

that this drug has been a favorite with those contemplating secret murder.

That its use for this purpose is constantly diminishing is wholly due to the gradually-increasing knowledge on the part of the general public that it is one of the homicidal drugs most certain of detection; and as modern chemistry has succeeded in removing much if not all of the mists and fogs which surrounded trials in past generations, the risk in the use of this poison has become so great that trials for murder with arsenic are becoming rarer year by year.

Yet, from time to time such cases do occur; and when they do, although the management of the trial must be wholly in the hands of the gentlemen of the legal profession, still they must rely largely upon the advice and assistance of the doctor. It is true, even if he be a medical examiner, his position is that of a witness only to tell what facts he knows, and such opinions as he can fortify; but he must also assist in clearing away any doubts which counsel eager in the defence of their client may seek to arouse in the minds of the jury while confining his own evidence within strict lines of impartial demonstration of scientific fact. The chain of proof in a trial for murder by arsenic will naturally include —

(1) The death and the cause of the death, namely, that it was arsenic in some form, and from nothing else; or, if from something else, directly, how far the arsenical poisoning was contributory thereto.

(2) That such death was the result of homicide, and not of suicide or accident.

(3) That the accused was the person who administered the drug, — this question involving motive, opportunity to administer, possession of the drug anterior to the crime, and other matters still more closely within the province of the lawyer.

It is with the first part of this chain of proof with which the doctor, and especially the medical examiner, has to do, and with the second part only to a limited extent. As in ordinary warfare inventions for defence have closely followed inventions for greater destruction, so in the legal warfare of murder trials, the skill of defence has been assisted by experience and the knowledge of increased means of medical proof, and to-day the closest attention to detail is necessary on the part of the physician. Formerly it would have answered every purpose to have demonstrated the presence of arsenic within the stomach. To-day such proof would be insufficient, as the presence of unabsorbed arsenic is consistent with a continuance with life. To-day the medical evidence must demonstrate not only the presence of the drug, but also, generally, that the drug has been absorbed, and also the method by which it has destroyed life, whether by the violent inflammation of the stomach and intestines coupled with the exhaustion of the violent vomiting and purging, or whether, at a later period, by the destructive effect of the absorbed drug upon the other viscera, notably the liver and kidneys, by producing fatty degeneration. A chemical examination of the vomitus and the urine voided, while of assistance in a capital trial, has not the importance that it would have in a trial for attempted murder where the victim survived, inasmuch as in such cases the proof of rejected and eliminated arsenic, combined with the history of the symptoms, would be the only proof of arsenic ingested or absorbed. But where death has occurred the pathological changes are so marked that it is not difficult to demonstrate that an irritant poison has been at work, and the chemist is able to demonstrate what that irritant was.

The medical witness must be prepared to demonstrate clearly the pathological changes. No jury would be warranted in finding a verdict of guilty in a case where, although chemistry might show a small amount of arsenic in the system, there was still no evidence that such arsenic had produced any deleterious effects upon the organism. This is of especial importance when the liability to error in attributing minute amounts of arsenic after Marsh's test to the presence of such drug in the body at time of death is considered. A still graver error is liable to result unless the utmost accuracy is observed in weighing the amount of organs delivered to the chemist, and also the amount retained for examination in case of accident to the first portions; for an error of little moment of itself, when multiplied for the purpose of forming an estimate of the whole amount in the body, would have a possible fatal effect on the life of the accused.

This was notably exemplified in the *cause célèbre* at New Haven, where two young men were put on trial for the murder by arsenic of one Jennie Cramer. Here, though *a priori*, from the place where the body was found, and from all the pathological conditions, the case was one clearly of death from drowning, as was later demonstrated to the satisfaction of the jury, the Government endeavored to establish the theory of homicidal arsenic poisoning.

In the report of the post-mortem examination there was absolutely no proof of any deleterious effects of the drug upon the organism; on the contrary, the condition of stomach and bowels showed the absence of either vomiting or purging, and no fatty degeneration of any organs, and no inflammatory action in the stomach. The chemist who analyzed portions of the organs and of the muscles, found, by Marsh's test, minute quantities of arsenic.

It is, of course, a question if there was any arsenic in the body during life; but when it was put in evidence that he had *about* one-half of the liver and *about* so much of other organs, and the minute fractions of a grain of arsenic in these *abouts* were multiplied, as if they were exact amounts, by the weight of the body, to produce an estimate of a little less than two grains in the whole body, a very dangerous plan was adopted, when human life was at stake.

This, however, belongs rather to the province of the chemical expert than the pathologist. It ought not to be a matter of great difficulty to demonstrate the changes produced by an irritant poison, and to undergo the ordeal of a cross-examination, when the poison has been the sole cause of death. When disease is present, or organic changes in various organs, it may not be so easy to make clear to a jury just how much the arsenic had to do with the death, especially if the quantity is small, and the exhaustion from the irritant action is the chief factor. Each case must be considered and treated of itself; and that evidence will have the greatest weight with the jury which does not claim too much, or assume infallibility. The present state of medical expert testimony in the courts would undoubtedly ensure a number of witnesses to controvert any extreme position, no matter how fully convinced the examining physician might be of the soundness of his theories.

In all trials where the results of chemical analysis show only a small amount of arsenic, the theory of accidental admixture after death will be urged, especially in those long buried. To-day not much weight, if any at all, is given to claims that the body absorbed arsenic from the soil in which it lay. The physician who makes the autopsy has only to demonstrate the caution he observed to prevent admixture from anything on his table or instruments, or the use of unclean dishes or jars, and leave to the chemist the demonstration of the impossibility of any artificial accidental admixture while the organs were in his charge. One thing is absolutely conclusive. No pathological change can occur after death. If the pathological changes of arsenic poisoning are to be observed in the body, it is entirely clear that the arsenic was ingested during life.

Most of the embalming fluids, so-called, contain arsenic; and it is often the case that the body has been injected before the cause of death is suspected. This need give the medical examiner no trouble; for the utter worthlessness of any pathological or chemical examination, as far as the demonstration of arsenic poisoning is concerned, is so clear that no prosecuting officer would proceed at all in the case, if the result depended on such examination. There were some such cases involved in the late trial of Mrs. Robinson; but they were not regarded as factors, either by the lawyers or physicians.

The question of accident, suicide, or homicide, is one to be determined by collateral evidence, and really to be decided by the jury. The form in which the drug was ingested, the quantity and time and place, social surroundings and mental conditions, may all have weight in arriving at a just conclusion; and the physician can be rather of service to counsel before trial in aiding him to a proper theory, than in actual testimony upon the stand.

The other questions occurring in arsenic trials are wholly within the domain of law, and so not within the scope of a paper before this Society.

REPORT ON RECENT PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

TETANUS.

VON EISELSBERG,[1] in Vienna, has had an opportunity to investigate six cases of tetanus clinically and experimentally. Four ended fatally. In four cases fragments of skin, wound secretion, and blood were investigated, and used for inoculation experiments. In two cases splinters were removed from the wounds. In four of the cases the wound had been fouled with earth, when received. V. Eiselsberg's results corresponds with those of most other writers, except that he did not succeed in finding tetanus bacilli in the blood. Inoculation of animals with wound secretion, particles of skin, and wood splinters removed from patients subsequently affected with tetanus, were successful. In one instance tetanus followed inoculation with fragments of such a wood splinter which had been removed from a fatal case of tetanus two and one-fourth years before. With reference to prophylaxis, v. Eiselsberg recommends that even the smallest wounds which have been inoculated with particles of earth or foreign bodies should be most carefully disinfected, and all foreign substances removed at once; that all bandage material — soiled dressings, etc., that have been in contact with a tetanus patient — should be burned; that such patients should be isolated; and that an especial set of instruments and apparatus should be used for their treatment.

Of interest in this connection are the investigations of Dr. Joh. Raum, in Warsaw,[2] who has made a series of experiments by inoculating rabbits with earth. Earth from Göttingen which had been carefully shut up in a closed glass vessel for three and one half years, as well as earth from different parts of Warsaw, produced tetanus after an incubation period of from two and one-half to four days. An investigation of the cream-like mass at the point of inoculation invariably demonstrated the presence of the "Nikolaier bacillus."

Wiedermann,[3] of Stuttgart, was successful in his inoculation experiments with fragments of a splinter of wood taken from a fatal case of tetanus, and with the pus from the same patient although he did not find the bacilli in the latter.

Guelpa,[4] also, after an extended investigation, has confirmed the statements already made by Nikolair, Rosenbach, Brieger, and others. He concludes that tetanus is an infectious disease; that it is not, contrary to the opinion of Verneuil, a disease of equine origin, notwithstanding horses show the greatest susceptibility to it; that the tetanic symptoms are the result of the "toxine" produced by the bacilli, which increase in number during the first outbreak of symptoms only at the seat of inoculation. In general, the dissemination of the bacilli throughout the body is rare, and only occurs, if at all, in the later stages of the disease. That the indications for treatment are: (1) the extermination of the bacillus colony by active surgical procedure; (2) the elimination of the "toxine" from the system by cathartics, diuretics and diaphoretics; (3) to prevent the excitation of the nervous system by large doses of chloral.

OPERATIVE TREATMENT OF HERNIA OF THE BRAIN AND SPINAL CORD.

Hildebrand[5] reports three cases of operative interference in Koenig's klinic, in cases where congenital defects existed in the cranial vault, with protrusion of its contents. One was a meningocele-cerebratis; another, an encephalocele, the sac containing fluid and brain tissue; the third, a meningo-cephalocele. All ended fatally. Also five cases of spina bifida, with three deaths from suppuration and meningitis, or unknown causes. Hildebrand recommends the following rules in operating:

In all cases of cerebral and spinal herniæ, when the contents of the sac are fluid, incise, evacuate its contents and remove it. If the contents be brain substance, it should be reduced, if possible, and held so with a truss. If irreducible, the contents should be excised. Ligation of the sac base, without opening it, is only to be done with meningoceles containing only small amounts of cerebrum. Escape of cerebro-spinal fluid is avoided by immediate introduction of the finger through the incision in the sac, and occlusion with its tip of the communication between it and the interior

of the skull. An elevated position of the seat of operation and narcosis are considered advantageous. The Schatz-Rizzoli methods are condemned.

THE REGENERATION OF BRAIN TISSUE AFTER TRAUMATIC LESIONS.

Coën and others have denied that a genuine regeneration of the cerebral tissue occurs, and claim that the newly-formed tissue contains no new nervous elements. In experiments during the past twelve months,[6] wedges of brain substance were excised from dogs, rabbits, and guinea pigs, or portions grafted from one hemisphere into the opposite one. Union generally occurred so perfect as to necessitate a careful microscopic examination to locate its site. A most complete regeneration of the cerebral tissue took place, the proliferation process at times being so active that the newly-formed tissue even rose above the level of the adjacent surface. Likewise an early and thorough union of the grafts with the adjacent surfaces occurred, except in those cases where a rather profuse bleeding occurred during the transplantation.

AFTER-TREATMENT OF TRACHEOTOMY.

Prof. C. Langenbuch,[7] Berlin, has tamponed the trachæ after trachotomy, on account of diphtheria, since 1882. For this purpose the low operation is performed, in order that the tampon can be introduced without interfering with the vocal cords. The tampon consists of small pieces of cotton soaked in an iodoform-ether solution. He claims that the percentage of recoveries has been raised from 22.4 to 36 per cent. The benefit of this method is especially marked in cases of tracheotomy in children under two and one-half years of age. His conclusions are based on the examination of 1192 cases, 593 of which have been treated in this way.

FURTHER IMPROVEMENTS IN THE TREATMENT OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS.

C. J. Symonds[8] contributes an interesting account of his experience in "tubage" of œsophageal strictures. His detailed account of his cases is instructive, and is suggestive of further benefits to be gained in the treatment of this hopeless affection. The subject he sums up as follows:

The short tube I have now used in twenty-two cases; of these, seventeen have died under observation, five of which have been already published, while notes of the remaining twelve are given above. Two cases were submitted to treatment for a short time only, and left the hospital relieved, but without tubes, and three are at present under treatment. Of the fatal cases, nine died with the tube in position, swallowing to the last: four were able to swallow without a tube for some time before death; in one a long rubber tube was substituted and worn in comfort for four months and a half. In one other, a long rubber tube was used for three weeks after eleven months of the short tube. In two the long tube of Krishaber was used after cough on deglutition ensued, and gave rise to much distress from ulcerations of the mucous membrone over the cricoid. The majority, therefore, wore the short tube up to the time of death, or were able to swallow owing to the dilatation effected. It will be seen that the patients lived variable times after treatment began, depending upon the duration beforehand and on the form of the disease. The longest periods were six, seven, eight, and eleven months. If it be granted, from the evidence of the results of post-mortem examinations and of the patient's sensations, that this form of tubage does not hasten the growth of the disease, then it seems quite clear that the patients are more comfortable than after gastrostomy; they die from the unimpeded and unhastened progress of the disease. The majority of the cases of gastrostomy succumb, probably not more than one in five recovering. Only once has an accident occurred to me or to my dressers in an experience now of twenty-two cases, and this was not due to any injury inflicted on the stricture, but to a perforation of the pharynx high up. Besides these twenty-two cases, all under prolonged treatment and under various hands, we have treated quite ten other cases by bougies without accident. It may be said, therefore, that there is no danger in passing bougies; a great deal too much stress has been laid upon this point of danger. I have passed tubes and bougies in all conditions, and so have my dressers, without, so far, any accident, save the one mentioned, and that occurred to myself, and might have been avoided, and now, with the new introducer, certainly will be in future. The improvement in the patients is remarkable: one man, as stated, gained nineteen pounds in ten days, but he was nearly dead before treatment; while others have gained flesh less markedly, all have been benefited. The delight of a man at being able to swallow again is well worth seeing. It seems almost a miracle to him. We last saw under treatment a postman who came unable to swallow. He was admitted for one night and treated as described above. A No. 7 was passed, and he returned to his duties daily. During Christmas week he was swallowing freely, and a longer tube had been passed. From a perusal of this case it will be seen that all were able to move about, and some to follow their usual occupation; when this is not laborious it may be carried on till the strength be reduced by the progress of the disease.

In conclusion, I would claim for this method of treatment — that it is applicable to nearly every case of malignant stricture, and probably to all if seen early enough; that it affords the patient far more comfort than the long feeding tube; that it is superior to gastrostomy in the comfort it secures and in the freedom from danger; that life is prolonged in every case, and as long as after the most successful gastrostomy; that the tube does not give rise to any irritation, being tolerated by the most irritable patient; that, instead of favoring growth, it checks it, by allowing unhealthy fluids to pass from the œsophagus into the stomach; that the use of the short tube — and, when cough on deglutition arises, of the soft rubber tube — will enable us to treat all cases without resorting to gastrostomy.

ON THE TREATMENT OF SO-CALLED PERITYPHLITIC ABSCESS.

R. F. Weir[9] has contributed an excellent paper on the above subject, based on the observation of one hundred post-mortem examinations, and from thirty-two personal operations for so-called perityphlitic abscesses, his conclusions are as follows:

(1) That all such abscesses originate in the peritoneal

[6] Prus. Wiadomosci Lekarskie, 1888, August, and Annals of Surgery, 1889, vol. ix, p. 225.
[7] Berlin Klin. Wchnschr., 1888, xxv, 44.
[8] Lancet, March 30 and April 6, 1889.
[9] Medical News, April 27, 1889.

cavity, and there develop to an appreciable size before invading extra-peritoneal tissues or viscera.

(2) That as stercoral accumulations or cæcal perforations are so rarely met with as causes of perityphlitic tumor or abscess, they should not be considered from a clinical view in any given case.

(3) That in an attack of perityphlitis originating, as it generally does, as a perforation, or as a gangrenous condition of the appendix vermiformis, all use of purgatives or enemata is in the beginning of a case to be avoided, and the immobilization of the patient is to be insisted on, and aided, if necessary, by anodynes.

(4) That if a tumor be found, it be opened by a lateral incision as soon as symptoms, constitutional or local, indicate the formation of pus.

(5) That if symptoms indicating an increase of the local peritonitis, such as the persistence of vomiting, spreading pain, abdominal resistance, and temperature elevation, continue with or without the formation of tumor, for a period of forty-eight hours, the danger of the disease is greater than the proposed lateral or median laparotomy, which should then be immediately resorted to. In many instances even a less time should be afforded the consideration of the disease before operating.

(6) If a general peritonitis be suspected, corroboration can often be obtained by abdominal aspiration with a fine needle employed in places other than in the right iliac fossa, and particularly by a deep, hypogastric puncture into the pelvis, the bladder being first emptied. However, if left in doubt, it is better to operate.

(7) (*Sub judice*). That if general suppurative peritonitis be found at a laparotomy, lateral or median, avoid too much handling of the intestines, and trust to either temporary irrigation with large glass tubes, (Tait's,) or, more rationally, to permanent or repeated irrigation and fluid distention of the abdominal cavity, as advocated by Greig Smith and by Penrose.

(8) (*Sub judice*) To meet the obstruction symptoms due to septic paralysis of the bowels, which often persists after a laparotomy for suppurative peritonitis, saline purgatives and repeated washing out of the stomach should be resorted to, even though vomiting be present to a marked degree. Enterotomy may also, in exceptional cases, be entertained.

CATGUT RINGS AS A SUBSTITUTE FOR BONE PLATES IN LATERAL ANASTOMOSIS OF THE INTESTINES.

Jessett and Horsley [10] have contributed an experience in experimentation in the forming of lateral anastomosis that clearly demonstrates its value. They reprint a large number of experiments, and give the results as follows: The operation, as at present practised by the Czerny-Lembert suture, gives a mortality of 86.6% as against 24.99% of enterorrhaphy by Senn's invagination method, and only 7.69% by the method of approximation plates. The time required by the Czerny-Lembert method, which necessitates fifty to sixty sutures, was an hour and a half; the method by Senn's plates required only twenty minutes, and needed but four to six sutures.

Abbe [11] has suggested the use of catgut rings instead of bone plates in the establishment of lateral anastomosis. The rings are made as follows:

"A moderately heavy catgut is chosen, taken from alcohol and juniper oil; it is wound loosely on a test-tube, and soaked in hot water. It soon kinks up, and, were it not on a tube, could hardly be unravelled. After a while it is straightened out, allowed to untwist, wound again loosely, and soaked in hot water once more, until it ceases to twist. It is then ready to make up into rings which will lie perfectly flat. Eight or ten turns over two pins, stuck in a cork two inches apart, will make a bundle somewhat smaller than a lead pencil. These may be tied at four places with fine silk, to secure the strands parallel while being wound round like a cable, with a continuous piece of the same catgut. The end of the piece is secured by threading it into a Hagedorn needle, and transfixing the whole bundle obliquely with it at the place of finishing. Thus there are no knots, and it is difficult to find the point of beginning.

"The ring is now a long oval, with an inside diammeter of two inches, and in thickness smaller than a a pencil. Six strong but small braided silk threads are now fixed to each ring, equidistant, on the face looking toward the other ring which is to be laid against it. No knots are used. A needle pierces the ring between the strands, carrying the thread, which is drawn through all but eight inches, and wound once and a half round, sinking between the encircling catgut, piercing the ring again, and cut off. The rings, which have now been water-soaked, are ready for use, if needed for emergency; but, if possible, they should be kept a while in alcohol, under pressure between two glass slides, the threads being curled up within the oval, and the sides being pressed together after the glasses are tightly tied together. The ring thus becomes a long oval with parallel sides, and soon becomes harder and flattened on its faces. Moreover, it shrinks a trifle in alcohol, to swell again in the intestine and give additional security.

"In using the rings, I find it saves time to have each thread have its own needle. The intestine is pierced from within outward less than a quarter of an inch from its cut edge. The ring should be laid on a damp folded towel, with threads in order and needles stuck in the towel, which is held by the assistant close to the bowel, while the operator quickly pulls the thread through and passes the ring into the interior of the bowel. When the threads are tied and cut off, the apposition is perfect, but by a quickly made running suture outside all, a half inch of peritoneal surface is at once secured beyond the possibility of a leakage. More than this is superfluous, for the edges held between the rings act as valves.

"In invaginating the end of the cut intestine after exsection, one will delay a long while if he tries to turn in first one and then the other edge, and will also find the mesentery try to turn in after it on the attached side. My rule is to trim back the mesentery at least a half inch from the end. Then seizing both lips with toothed forceps, plunge them directly into the lumen. The entire edge usually follows, and one holds them by the left index finger and thumb while a quick running overhand suture of the slit thus formed is made."

COLECTOMY FOR MALIGNANT DISEASE.

Kendal Franks [12] reported two cases of malignant disease in which operative proceedures were undertaken. A statistical table, which accompanied the

[10] Lancet, March 16, 1889.
[11] Medical News, June 1, 1889.
[12] Lancet, March 2, 1889.

paper, gave details of the fifty-one cases hitherto published, including the operation and date, the seat of the disease, the length of gut removed, the treatment of the resected intestine, the situation and length of the wound in the abdominal wall, the result, and the reference to publication. From this list it appeared that the first operation was done by Reybard, in 1843, and was successful, the patient living for a year afterwards; and the list included cases by Messrs. Bryant, Marshall, Treves, Sydney Jones, Whitehead, and Pitts, in this country.

From a consideration of the cases, which numbered fifty-one, it appeared that the operation had proved fatal in 40.8 per cent. In twenty of those which survived operation the disease returned in ten, and in the remainder the period which had elapsed was too short to draw conclusions from. One case was alive four years after operation. The author drew the following conclusions: — (1) Colectomy rarely effected a cure. (2) As a palliative measure it was justifiable, and frequently demanded. (3) Recurrence usually took place in the liver or mesenteric glands, and death then was much easier than when the intestine was occluded. (4) The mortality after immediate suture of the intestine and after the formation of an artificial anus, was nearly equal. (5) Immediate suture of the divided ends was preferable to the formation of an artificial anus. (6) The death-rate had been reduced in the latter cases, and a further reduction might be anticipated.

(To be continued.)

Clinical Department.

TETANY TREATED SUCCESSFULLY WITH URETHAN.[1]

BY DR. S. L. ABBOT.

A SEVERE case of tetany was under my care in the Massachusetts General Hospital, two years since, which yielded promptly to treatment with urethan.

The patient was a robust "'longshoreman," forty-three years old, accustomed to hard work. With the exception of an attack of typhoid fever five years before, he had been a uniformly healthy man. His habits were temperate. Six weeks before entrance he had been attacked, without any known cause, with severe cramps, which came on at first in the early morning, affecting primarily his legs. The spasms steadily increased in severity, affecting in time all the flexors of the extremities, the abdominal muscles in part, the outer muscles of the thighs, and those about the shoulders. They increased in frequency, so that on some days they occurred every half hour, and were easily excited by any muscular effort. Even crossing a foot over the knee of the other leg for the purpose of tying his shoe, would bring on a cramp of the flexed leg, extending up to the abdomen and involving the abdominal muscles of that side. For a few days before admission to the hospital he had suffered from darting pains here and there in the back of the neck, the chest and legs. He thought the attacks were somewhat relieved by micturition.

At the time of entrance the patient complained of pain down the outside of the left thigh, extending from a point near the left sacro-iliac synchondrosis, where he was very sensitive on pressure.

There was no apparent loss of strength. General sensation was normal, and the special senses were not affected. There was no headache. The appetite was poor, and the bowels were regular. Micturition was somewhat frequent, but nothing abnormal was detected in the urine, which was normal in color but of low specific gravity, 1005.

During his first night in the hospital the patient had one attack of cramps.

When first seen by me on the following morning, having in mind the very prompt effect which I had obtained in checking the spasms in a violent case of chorea by the administration of urethan,[2] I determined to try it in the present instance. Ten grains were prescribed to be given every two hours by day, the dose to be increased to fifteen grains at bedtime. Diet, six ounces of milk every two hours.

The patient had one or two attacks of cramps during the day, one of which was seen by my assistant, Dr. Jacobs. There was no general convulsion nor loss of consciousness, but there was a tonic contraction of the legs and left arm lasting about half a minute. The patient slept well most of the following night, having two or three slight cramps with little pain. On the following morning the general pains complained of on entrance had entirely disappeared. The tongue was covered by a thick moist coat.

On the next day the patient reported no cramps for twenty-four hours, and he was feeling generally much easier. Diet: soup, broth, milk, bread. Urethan to be continued.

Two days after the patient had had no more cramps, but he complained of some pain in the course of the sciatic nerve in the left thigh. This was less the next day and there was no return of cramps. On the ninth day after the treatment was commenced the patient was on full diet, sat up all day free from pain, and there had been no cramps since the second night after entrance. The urethan was omitted on the following day, and on the next he was discharged well. The temperature on entrance was 101.4°, and normal every day after. Pulse 100 on entrance, and ranged from 50 to 60 up to the last day, when it was 98.

It should be mentioned that previous to entering the hospital the patient had tried rest from work for a week without any relief to the cramps. Nine months after leaving the institution he was heard from, and reported that he had continued in perfect health.

PARTIAL PLACENTA PRÆVIA IN AN EIGHTEENTH PREGNANCY.

BY A. J. ABBE, A.M., M.D., OF FALL RIVER.

MRS. O., a native of England, forty years of age, was seven months advanced in her eighteenth pregnancy, when, on May 24th, she was suddenly seized with hæmorrhage from the uterus. Upon my arrival I found her not flowing, but a vessel contained about two quarts of blood. On examination the baggy feeling over and behind the slightly dilated os confirmed the diagnosis of placenta prævia. Rest was prescribed, and the probability of the necessity for induced labor was explained.

[2] Boston Medical and Surgical Journal, vol. cxiv, p. 419.

Five days later she had another hæmorrhage a little less in amount. I did not see her. A week later she had a third, and fainted. I advised immediate delivery, but was unable to obtain the consent of any member of the family, or even permission for a consultation. Impressing upon them the danger of delay, and leaving the responsibility with them, I departed. At intervals of five to fourteen days she had four more hæmorrhages. General malaise was marked throughout; "fainting spells" were frequent.

On July 5th, labor pains continued for several hours, the os becoming the size of a silver quarter, with but slight hæmorrhage. She was now willing to have anything done, but it was my turn to delay a little. Pains ceased until July 20th, when contraction again occurred for three hours, and then ceased for eight hours; when, upon my arrival, I found the os two-thirds dilated, head presenting. Drawing four ounces of residual urine, I dilated manually for a few moments, and ruptured the membranes; when contractions recurred and completed the dilation in thirty minutes (O L. A). Second stage lasted fifteen minutes; third stage, fifteen minutes. The placenta presented upon the lower edge of its maternal aspect an elliptical surface, three by one and three-quarters inches, which was smooth, and glazed with a membrane similar in all respects to the amnion. One drachm of ergot was given. Very little flowing. Mother and boy both well.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

F. B. HARRINGTON, M.D., SECRETARY.

MEETING of May 27, 1889. DR. W. L. RICHARDSON, President, in the chair.

A CASE OF TETANY

was shown by DR. F. C. SHATTUCK.

A characteristic spasm was excited in the right arm and hand by pressure applied below the clavicle, and prompt relaxation was induced by the application of the constant current, — the negative pole on the sternum, the positive on the extensor surface of the arm and wrist. The patient was a well-developed, vigorous girl of twenty-one, who underwent a very severe attack of diphtheria, followed by paralysis of the fauces and right leg, five years ago. After recovery, she began to experience occasional cramps in the right hand, without prodromata or apparent exciting cause. The spasms were, at first, confined to the right hand and arm, lasted only one or two minutes, and were separated by considerable intervals. Gradually they have involved the other upper and lower limbs; sometimes now last an hour, and are much more frequent. Several days ago, in the midst of an attack, she sought advice at the Massachusetts General Hospital, and was admitted to the ward, the attack being promptly recognized by Mr. Chadbourne, the medical house officer. The Trousseau phenomenon is well marked, it being easy to bring on spasm in either or both arms by pressure in the axillary or clavicular regions. She has had two attacks in the left leg since entrance, but pressure on the nervous and vascular trunks of the legs has failed to invoke spasm. The case is thoroughly typical of a somewhat mild form of the disease, except that the peculiar change of electro-muscular contractility, first described in connection with this disease by Erb, is not present, negative closure producing contraction when the current is applied to the nerve before positive closure, in this case, as in normal conditions.

The only disease to be eliminated in the diagnosis of this case is hysteria, and that can be easily excluded by the intermittent and bilateral features of the spasms, and by the total absence of any other hysterieal manifestation. In a case I reported[1] several years ago, the only other I have seen, the patient was a young man, and the spasms began and were very marked in the masseters, but were also severe in the trunk and limbs alike. The possibility of tetanus had consequently to be considered. The prompt relief which is brought in this case by the local application of electricity — both currents seem to act equally well — is noteworthy, and is not mentioned in any work on the subject which I have thus far consulted. My other case was cured by bromide and chloral. I propose to give this patient the former alone.

DR. F. C. SHATTUCK also showed

TWO RENAL CALCULI

voided by a hospital patient under the following circumstances. A woman of middle age was admitted, and a diagnosis of debility was reached after careful and thorough examination. She was doing well until a week ago, when she complained of moderate dysuria, for which no explanation was found in the urine. A few days later she passed two facetted stones, one as large as the terminal phalanx of a woman's little finger, and, immediately afterwards, urine perfectly loaded with pus. The next urines were clearer; and thirty-six hours after the stones came away the renal secretion was again perfetly normal. After the passage physical examination of the lumbar regions was as barren of results as before; and the lax and thin abdominal wall permitted thorough palpation. In the hope that we might ascertain which ureter was traversed by the calculi, DR. O. K. NEWELL was so kind this morning as to make an endoscopic examination. He reports that he saw both orifices, and that the left ureter seemed somewhat dilated.

DR. S. L. ABBOT reported

A CASE OF TETANY TREATED SUCCESSFULLY WITH URETHAN.[2]

DR. F. C. SHATTUCK read

SOME REMARKS ON TYPHOID FEVER, WITH AN ANALYSIS OF ONE HUNDRED AND TWENTY-NINE CASES TREATED IN HOSPITALS, AND SPECIAL REFERENCE TO RELAPSE.[3]

DR. GEORGE B. SHATTUCK thought the position taken by the reader with regard to relapse was a sound one. These views accorded with those adopted by most recent authorities upon typhoid fever, and would probably be found to be in accord with the experience of practitioners having extensive opportunity for observation. The fact that relapse was independent of indiscretions in diet was incontestable, and abundant proofs were to be found in any large hospital service, having numerous cases of typhoid fever, by any one

[1] Journal, 1887, i, p. 497.
[2] See page 230 of the Journal.
[3] See page 221 of the Journal.

who chose to look for them. It was certainly very desirable that this fact should be thoroughly understood by the profession; he thought it questionable, however, whether it was equally desirable that it should be dwelt upon with the laity. There were real dangers and drawbacks attendant upon early indiscretions in diet after typhoid, and it was difficult enough under any circumstances to restrain the greediness of the half-starved fever convalescent.

The trouble with Brand's statistics is that they are too good. A moderate experience with his method has not induced its adoption outside of Germany and Lyons. A proper application of the method demands plunging the patients in cold water from the very beginning of a febrile process, subsequently called typhoid fever, every time the temperature reaches a certain point. If the claim now made is, that the object of this constant disturbance of the patient is simply the stimulation of the nervous centres, Dr. Shattuck had sufficient confidence in the ingenuity of physiologists and the resources of therapeutics to suggest methods of stimulation as effective as the cold bath, and more agreeable, and at the same time less cumbrous, less disturbing, and less costly in our country, both for patients and attendants.

DR. F. C. SHATTUCK said, in reply, that until lately he has been disposed to take somewhat the same view of Brand's statistics, namely, that they are too good; but the evidence of other Germans, and especially of the French who are not prejudiced in favor of German ideas, is too strong to be disregarded. A more or less thorough Brand treatment has now been carried out in Lyons for fifteen years, with the best results, and the method seems to be winning its way in the French army hospitals.

DR. ABBOT said: It was very difficult to explain the cause of relapse in typhoid fever, or of the sudden rise of temperature which sometimes occurs in its course. It was certain that a very critical condition, such as unhealed ulcers in the intestines, might exist during apparent convalescence which gave no outward sign. He mentioned the case of a young man affected with typhoid, under his observation some years since. He had been left in his charge by the late Dr. Cabot, during a temporary absence from the city, and became apparently convalescent. He was so well that he was able to be up all day, and made no complaint. On Dr. Cabot's return home he resumed charge of the case. At his last visit Dr. Abbot gave the patient very strict directions about his diet, cautioning him against indiscretion, and assuring him that he was not yet out of danger of accidents, and he promised to be guided by his advice. On the next day, however, without consulting his physician, he ate a raw apple, which killed him. Severe abdominal symptoms at once came on, which ended in perforation of the bowel, peritonitis and death.

DR. WHITTIER said: It is very evident, Mr. Chairman, that not much other than words of commendation can be said of Professor Shattuck's paper and the subject it places before us for discussion. He has not left much to be said on this most important and timely topic of cold bath treatment of fever, and particularly of typhoid fever.

The figures and the conclusions set forth in the paper present to us incontestable evidence of the need of a change from our long-practiced method of dealing with high temperatures, for figures like these are facts, and conclusions such as are here drawn are safe guides for treatment. It is only recently that it has been conceded by any considerable number of practical, every-day practitioners, that the underlying principle in the cold-bath treatment of fevers is more and better than the abstraction of heat already generated in the tissues, and that, after all, the influence on the nervous system, stimulating to new effort and imparting new power, is the chief effect of cold applied to the surface of the body; and the number of converts to this recently established view is constantly increasing, and in my opinion must continue to grow as men become better informed. We all recognize the obstacles to putting in practice the cold-bath treatment of fevers; large obstacles to the proper adjustment of the mechanical appliances. For instance, the bath should be at the bedside of the patient — an extremely difficult thing to arrange in private practice; we note the need of larger attendance and attention, for the patient must be lifted and not allowed to make any effort whatever; and yet larger difficulties in overcoming popular prejudice against so great an innovation, so radical a departure from previous and well-established methods. But our duty in the matter is none the less clear and positive, and it rests with the profession to insist upon and to carry out the changes in treatment advised and urged by Professor Shattuck.

DR. J. P. REYNOLDS: Many instances of genuine typhoid cases, in which the typical course of the disease and its distinctive features are well marked, will, provided they occur in private practice, and therefore come early under judicious control, recover safely without other management than utter rest of mind and body, the securing of sleep, the simplest form of nourishment, a free use of diluents, and the very slightest medication. With this in mind, would any physician subject an average case of typhoid under his own roof to the continuous application of cold water?

Several speakers have referred to the habit of accrediting relapses to errors in diet. Were that fact generally kept in mind, upon which Liebermeister, in "Ziemssen" so justly lays stress, that no matter what improvement appears in pulse, in temperature, or in general condition, the risks of typhoid are continually present in every genuine attack for not less than thirty days; that at least until that time has passed the attendant must unshrinkingly exact entire tranquility of body and mind, relapses would be seldom if ever known. Errors in diet, rightfully interpreted, mean almost unfailingly, criminal disregard of the all-important clinical truth, that during the whole term mentioned diseased conditions invariably persist.

All that the limits of this discussion strictly permit has perhaps now been said; but one statement, many years since forcibly urged in a leading article of the *British and Foreign Medico-Chirurgical Journal*, appears of such paramount importance as to warrant its repeated mention whenever the treatment of typhoid comes up. The writer of that article maintained that if by simple means, for example, *pro re nata*, once, twice or three times daily, some such pill as the following,

Powdered Rhubarb	2 grs.
Comp. ext. Colocynth	½ gr.
Ext. Hyoscyamus	5-6 gr.
Oil of Caraway	q. s.

adding, in case of need, a simple enema, a daily dejection, fæcal in character, be secured during the first week of typhoid, the graver symptoms of the follow-

ing period, which he thought justly characterized as those of septic poisoning, would not, to any marked degree, occur. Where such a care has been neglected it is believed that the best key to subsequent successful control has been lost.

No one questions the inestimable value of diagnosing early and of treating promptly every variety of grave disease, but this is never more indispensible than during the onset of typhoid; and the clinical gain would be immense, did every practitioner feel himself under bonds at least to entertain the question of impending typhoid, whenever, in the absence of distinctly localized inflammations, two conditions exist, inability to keep any longer erect and utter disappearance of appetite.

Dr. F. E. Cheney reported

AN UNCOMPLICATED CASE OF PROGRESSIVE OPHTHALMOPLEGIA EXTERNA, OR A SYMMETRICAL PARALYSIS OF THE EXTERNAL OCULAR MUSCLES.[4]

Dr. Wadsworth: The case reported by Dr. Cheney is a very interesting one, if for nothing else, from its rarity. It is the only entirely uncomplicated case of ophthalmoplegia externa that I remember to have seen. Such cases I believe are nuclear. Ophthalmoplegia complicated with other symptoms is not very rare. A number of years ago I showed a patient at this society with locomotor ataxia and ophthalmoplegia externa and interna. A few years ago I reported a case of ophthalmoplegia externa and double optic neuritis, apparently due to lead poisoning. At one time I was inclined to regard this case as one of nuclear disease, but am now disposed to think it one of peripheral neuritis. The paralysis of the ocular muscles was acute, and was entirely recovered from. Three days ago I saw a man of fifty years of age with ophthalmoplegia and simple optic atrophy. The ophthalmoplegia had begun twelve years ago, with sudden dropping of the left upper lid; the date at which the right eye was first affected is uncertain. Failure of vision was first noticed six or seven years ago. There is now in the left eye no perception of light; complete paralysis of all the ocular muscles; the right eye counts figures at two feet; ptosis is only partial, but all the other muscles are paralyzed except the superior oblique. It is remarkable that, with total inaction of all the other muscles, the right superior oblique appears to act with normal vigor. I discovered no other symptoms; there was nothing to point to locomotor ataxia, but I was unable to make an exhaustive examination at the time, and hope to have opportunity for further investigation.

Dr. Bullard stated that it was now generally admitted that chronic progressive total opthalmoplegia externa was always nuclear, and the lesion in these cases was disease and destruction of the cells of the nerve nuclei, similar to that which occurred in the gray matter of the cord in progressive muscular atrophy.

Dr. Wadsworth: I should like to say a word as to the nomenclature. Hutchinson first applied the term ophthalmoplegia externa to cases in which the external ocular muscles were paralyzed, in distinction to cases of paralysis of the internal ocular muscles, which he called ophthalmoplegia interna. But he soon after published a series of cases under the former title, in many of which the internal muscles also were paralyzed, and there were other complications. I quite agree with what Dr. Bullard has said regarding the nuclear origin. The term, I think, should not be applied unless more than one nerve is involved. The cerebellar affection referred to by Dr. Prince, involving the red nucleus, and so the fibres of the third nerve as they pass through it, would only affect one of the ocular nerves, and in such case the term would not be appropriate.

Dr. Walton: In connection with the question of neuritis, as causing symptoms similar to those of ophthalmoplegia, I should like to mention a case which I saw at the Eye and Ear Infirmary, at the request of Dr. Sprague. The patient was a middle aged man, who had complete immobility of the globe, together with lid drop in both eyes. He also had, however, optic atrophy and tenderness of the extremities, together with diffuse numbness and motor weakness. It was, therefore, a typical case of multiple neuritis, affecting, among other nerves, those whose nuclei are commonly attacked in ophthalmoplegia. The cause was probably tobacco. I do not mention this case with a view of advancing the theory that neuritis is the cause of the disease under discussion (which I think is undoubtedly nuclear, and analogous to bulbar paralysis), but to call attention to a possible source of confusion in diagnosis.

Dr. Cheney said: Dr. Prince must have misunderstood my statement in regard to paralysis of the intra-ocular muscles in this disease. My statement was: — "The intra-ocular muscles, in the uncomplicated form of the disease, do not suffer." I have examined the reports of between twenty and twenty-five of the uncomplicated cases, and in none of them were the intra-ocular muscles affected.

FIFTH DISTRICT BRANCH OF THE NEW YORK STATE MEDICAL ASSOCIATION.[1]

Dr. T. H. Allen, of New York, read a paper on

TRAUMATIC PELVIC CELLULITIS.

This cellulitis, he said, was always associated with a unilateral or bilateral laceration of the neck of the uterus, and much more frequently with the former because this was almost always deeper than the bilateral tear. He did not believe that in every case of laceration the involution of the uterus is arrested; but numerous examples of subinvolution, associated with laceration, had led him to consider the relation of cause and effect to the positive and direct. He then proceeded to the narration of cases.

Case I. Mrs. R., aged twenty-nine years, has had three children, the last two of whom are living. After her last labor, nearly eighteen months ago, her health began to fail. The flow did not cease entirely until three months. Since her confinement she has become pale and anæmic; has had intense headache, radiating anteriorly and posteriorly from a point on the vertex, and also attacks of syncope increasing in frequency; pain in back and left iliac region; frequent micturition. Examination: Left lateral laceration, one-quarter of an inch in depth; uterus much enlarged; length of uterine cavity, three and one-half inches; thickening beyond the utero-vaginal junction in left broad ligament, circumscribed and intensely tender to touch. Tonics were given and hot water used faithfully after

[4] See page 224 of the Journal.

[1] Concluded from page 213 of the Journal.

the manner advised by Emmet, but the tenderness persisted. Trachelorrhaphy was then performed in the usual way, five silver sutures being inserted. The patient was placed in bed and her water drawn with the catheter every six hours. Union was complete, and at the time of her getting up there was no tenderness, and the heat and pain on the left side had markedly diminished. She rapidly got well, and continues so at the present time, two years after the operation. The uterus measured two and one-half inches six weeks after the operation.

CASE II. Mrs. P., age twenty-nine; one child, stillborn, two years previous to consultation, labor tedious, instrumental delivery, lochia continued ten weeks. Since then her health had become seriously impaired; loss of flesh and strength; general facial acne; recurring hemicrania; pain in back and left ovarian region; irritability of bladder, dyspareunia; mental depression, and irritability; lack of self-control; suspicion; jealousy. An examination showed unilateral laceration of cervix and traumatic cellulitis of left broad ligament. The patient having already used hot water injections, under the advice of her physician, the operation of trachelorrhaphy was performed five days later. This was successful, and two months after operation she felt much better and her acne had almost entirely disappeared. There was no pain or tenderness remaining, and she was bright and cheerful. Since this time, over a year ago, the patient, whose marital relations were previously strained, has lived happily with her husband.

Having related four other cases, Dr. Allen said it must not be inferred from these that he is prone to operate in laceration complicated with cellulitis. This he would do only in exceptional instances. The opinion of the best gynæcologists he believed was expressed in the following quotation upon a paper read by Dr. C. C. Lee, before the Medical Society of the County of New York, in 1881. "When any decided inflammation exists about the uterus, or so long as any tenderness can be detected in the neighboring connective tissue, it is unsafe to operate." It was also true, however, as stated by Dr. Bache Emmet, in the "American System of Gynæcology." "In other cases the indurated and sensitive angle of laceration will be very marked and easily detached from the first, and in these cases there can be no question as to the necessity of removal of such a foreign body as a cicatrix." In this statement he thought Dr. Emmet had touched the keynote of the treatment, for he believed that this foreign body was the cause of the coëxisting cellulitis. There was a limited class of cases in which the use of copious intra-vaginal injections of hot water and other well-directed local as well as general treatment might improve, but not cure, a coëxisting cellulitis. This class of cases broadened the field for trachelorrhaphy, and to it, Dr. Allen said he had given the designation "traumatic pelvic cellulitis," to distinguish it from the more diffuse form of pelvic inflammation. It was primarily occasioned by a wound — a tear — and nature in her unassisted efforts to repair the loss of continuity in the uterine neck, built up a structure histologically different from the adjacent tissue, which operated in the same way as a foreign body. It was like cellulitis in the forearm of an insane woman, occasioned by stigmatization with small pieces of glass. The wound healed with the glass spiculæ remaining in the areolar tissue, but there was left a chronic form of inflammation which did not suppurate, but which resulted in cellular thickening, attended with pain and slight swelling, which increased to-day and diminished to-morrow, until finally relieved by excision. The operation of trachelorrhapy removed the cicatricial tissue (the foreign body) and completed the sphincteric arc of the neck with tissue identical in character, while it also had the effect of relieving by the bleeding caused by it, the congested blood-vessels and lymphatics, and of imparting a new impulse to the processes of nutrition. In concluding, Dr. Allen recapitulated the points of his paper as follows:

(1) Lacerations of the cervix uteri may result in the formation of cicatricial tissue which produces chronic traumatic pelvic cellulitis.

(2) In a limited number of these cases, local or general treatment, or both, will not subdue this inflammation and pain.

(3) Such treatment having failed, trachelorrhaphy may be performed successfully.

(4) The dense mass of cicatricial tissue operates similarly to a foreign body, and its removal by Emmet's operation is a logical remedy which precludes the possibility of its re-formation.

AFTERNOON SESSION.

DR. J. A. WYETH, of New York, gave an analysis, with comments, of a number of

IMPORTANT SURGICAL CASES

recently treated by him. They comprised supra-pubic lithotomy and other operations upon the bladder, ligation of arteries for various conditions, amputations and resection of the knee-joint. In regard to supra-pubic lithotomy, he said that after a career of varying fortune, in which at times it was unduly lauded and at times entirely abandoned, he believed this operation had now attained a secure position, which, on account of the improved facilities at the command of the modern surgeon, it would maintain permanently in the future. He also mentioned the various conditions in which it was applicable and in which it was, in his opinion, decidedly preferable to perineal section.

DR. J. G. TRUAX, of New York, read a paper on

THE TREATMENT OF ACUTE LOBAR PNEUMONIA.

Within the last four months he said he had attended fifty cases of this disease. Of these he related two cases representing the conditions requiring the greatest variation in the treatment. The first was a patient in middle life, of medium size, and fairly well nourished. All the ordinary symptoms and signs of pneumonia were present, but the attack was not of great severity. The temperature two or three degrees above normal, the pulse rarely above 100, no delirium, no albuminuria, and the crisis occurring in from five to ten days. This class of cases comprised about one-half of those met with by the physician, and nearly all such patients would recover, whatever the treatment adopted.

In the second class of cases, while the difference in the physical signs might not be very great, the clinical history differed widely, and to conduct such a case to a favorable termination required all the care and skill of the intelligent physician. Here albuminuria and delirium were almost always present, the temperature rose to 104° or 105°, and the pulse was from 120 to 140; while there was great embarrassment of the respiratory circulation, and consequently a labored heart action.

Dr. Truax said he had tried almost all kinds of treatment, other than venesection, to relieve the heart when obstruction to the pulmonary circulation was very great, and death from heart failure imminent; but with no great success. He lost five patients in succession (all Italians) from this cause, none of whom had more than one lobe of one lung affected, and all having the appearance of comparatively robust men. With this experience before him, to take from such patients venous blood, thus relieving the right heart, and also to some extent diminishing the pulmonary congestion, appeared to him to be rational treatment. Accordingly, the next five patients coming under his care, who seemed to be in great danger of dying from heart failure, were bled; and they all recovered, all the more aggravated symptoms improving immediately after the venesection. He found also that, after bleeding, small doses of antifebrine and quinine were efficient in controlling the temperature and pulse for a long time, while, given in large doses before bleeding, these drugs produced no effect in the same cases.

Dr. Truax then proceeded to give a condensed report of the five cases bled; after which, he suggested the following general rules for the treatment of acute lobar pneumonia. When the patient is first seen, unless it is contraindicated, a brisk cathartic. Should there not be much embarrassment of the pulmonary circulation or a very high temperature, the treatment should be expectant, a liberal milk diet being all that is ordinarily required. When there is great dyspnœa, high temperature, and a rapid, bounding pulse, active treatment is called for; and, to relieve these symptoms, the patient should first be given ten grains of quinine and three grains of antifebrine every four hours until some improvement is noted. Should improvement not occur within twenty-four hours, venesection should be resorted to, and enough blood withdrawn to relieve the patient. In the five cases reported, from eleven to seventeen ounces were taken; and Dr. Truax said that his experience had led him to believe that bleeding will save many patients when all other means would prove fatal.

Dr. Alfred L. Carroll, of New York, said that there could be no doubt that, in many cases of pneumonia, the need of arterial sedatives was manifestly indicated, and of all arterial sedatives venesection was the most powerful. There was, however, a third class of cases, not referred to in the paper, in which stimulus was urgently demanded on account of the feebleness of the patient. Take, for instance, he said, the average seamstress of the city. In the second class mentioned by Dr. Truax, there was danger of asphyxia, in other words, of the patient's drowning in his own fluid. In such cases, he did not think any intelligent physician, at the present day, was afraid of drawing blood from the arm. The lungs were engorged with blood, and the heart's action embarrassed, and venesection did not cure the pneumonia, but simply removed an obstruction. It was not, therefore, to be regarded as a curative; and in many instances, other arterial sedatives were sufficient to secure the desired end. When these other sedatives failed, it was unquestionably the physician's duty to resort to the lancet. The albuminaria spoken of by Dr. Truax, as occurring in many severe cases of pneumonia, was an indication of the venous congestion met with everywhere in the system.

Dr. E. R. Squibb, of Brooklyn, inquired whether Dr. Truax had ever used veratrum viride, the old substitute for venesection, which often accomplished what venesection would, in cases where the latter was inappropriate. He also asked whether Dr. Truax knew that he could get antifebrine for half the money if he bought it under its other name of acetanilide. The name antifebrine had been patented simply for the purpose of making money, and the same drug sold under that name cost double the price it did under that of acetanilide.

Dr. Murray, of Brooklyn, said that, by giving veratrum viride in doses of from half a drop to two drops every half-hour, he had never met with any difficulty in reducing the temperature. He was in the habit of carrying the drug to the extent of producing nausea; when he gave Dover's powder, and afterward stimulus, if it was required. Personally, he much preferred veratrum to venesection; and he should certainly give it a trial in any case before he resorted to bleeding.

Dr. C. S. Wood, of New York, said that, in former years, it was often noted that veratrum viride and antimony had a marked effect if they were administered after the patient had been bled, but did not exert their appropriate action if given upon venesection. He was firmly convinced that, in the class of cases described by Dr. Truax, there was nothing that could compare in efficiency with bleeding.

Dr. Truax, in closing the discussion, said that he entirely agreed with Dr. Carroll, that, in feeble patients, stimulants were clearly called for; and it was his practice to use them freely whenever they seemed indicated. In reply to Dr. Squibb, he stated that he had often tried veratrum viride; but cases were sometimes met with in which neither it nor anything else would take the place of bleeding.

Recent Literature.

A Text Book of Pathology, Systematic and Practical. By D. J. Hamilton, M.B., F.R.C.S.E., F.R.S.E., Professor of Pathology, University of Aberdeen. Vol. 1, pp. ix, 736. MacMillan & Co., 1889.

With each year the scope of a text-book of pathology increases, and from simply describing the appearances of the tissues and organs after death it now includes an inquiry into the causation of the various phenomena of disease, elucidated by experiment and bedside observation. It has to deal with pathological physiology as well as anatomy.

In the book before us the subject has been treated in this comprehensive way, to be completed in a second volume which is shortly promised.

The first part of this one is devoted to pathological technology. The manner and method of making post mortem examinations; the preparation of tissues and organs for microscopic work; and the obtaining and cultivation of bacteria.

To the methods of making autopsies which have been in use for the past twenty years, little that is new can be added, and the slight modifications advanced are rather to be regarded as personal preferences than any real advance. The author prefers opening the brain by a series of transverse vertical cuts through the whole organ, to first separating the hemispheres by a series of longitudinal ones. This is certainly the

best method, if the brain is first hardened in Müller's fluid, as lesions can thus be localized with far greater accuracy than when simply examined in the fresh state at the time of the autopsy.

The part devoted to microscopic technique shows a thorough acquaintance with the subject, and only well-tried and thoroughly approved methods are given. It is especially explicit in directions for the use of the freezing mixture, which is greatly preferred for general use.

The part devoted to bacteriological methods adds but little, as it is not full enough to be of great practical value; for this department has become so extended as to be entirely beyond the field of the general pathologist, and its manipulation should be left to those who have had the extended training of the specialist.

The last part of the volume takes up general pathology and a few subjects in special pathology. In the arrangement there is nothing strikingly new. The latest information is given, however, without too strong a presentation of the author's personal views. But there is evident, throughout, original investigation on his part which carries weight in his judgment of the work of others.

The blood, heart and blood vessels are taken up in the special part and are fully gone into. The normal conditions are always placed before the reader for comparison, and are of great value in this respect. The numerous illustrations are mostly original and clear cut.

We can highly recommend the book as containing a great deal that is very good, clearly arranged and indexed, and if the second volume carries out the subject as well as it has been begun, the work will be a valuable contribution to our text books on pathology in the English language.

Studies in Pathological Anatomy. By FRANCIS DELAFIELD, M.D., Professor of Pathology and Practical Medicine, College of Physicians and Surgeons. Vol. II, Part III. Acute Bright's Disease. Pages 37–64, plates xl–lxxxii. Wm. Wood & Co. 1888.

This is a continuation of a work begun several years ago, of which the preceding parts, treating chiefly of inflammation and diseases of the lungs, have already been noticed.

As the title indicates, this number deals with the kidney. It is the aim of every one who has studied the subject to bring under general heads the various lesions which are found on the post-mortem table, and refer them to some systematic classification. This has been attempted here. The author first gives a capital short resumé of the various views that have been advanced since the time of Bright, and the successive advances which have been made in our knowledge. He then gives his own idea, and classifies all the diseases under the two general heads of Acute or Chronic Bright's Disease.

The former is alone considered here, and is subdivided into acute exudative nephritis, acute degeneration of the kidney, and acute diffuse nephritis. The first is defined as "an acute inflammation of the kidney, characterized by congestion, an exudation of plasma, an emigration of white blood cells, and a diapedesis of red blood corpuscles from the vessels, to which may be added swelling or necrosis of the renal epithelium and changes in the glomeruli. This form may be primary, but generally is a complication of the acute infectious diseases." The second subdivision is "characterized by degeneration or death of the epithelial cells of the tubules, and is caused by the infectious diseases, severe inflammations, and poisons, such as arsenic, mercury, and phosphorus." The third form he regards as the most serious and important. Its lesions are those belonging to the acute exudative type, with two additional changes: (1) A growth of connective tissue stroma; (2) a growth of the capsule cells of the malpighian bodies. This is one of the forms of scarlatinal nephritis. It occurs early and late in the course of diphtheria, is the most important variety of the nephritis of pregnancy, and it is especially frequent as a primary nephritis, with or without a history of exposure to cold."

As presented here we fail to see that there is anything essentially new in his classification, or that there is any distinct advance made. For our own part, we fear that hard and fast lines cannot be drawn, and that, although there appear to be certain end types which are fairly distinct from each other, that there also occur numerous intermediate and mixed forms which will always with difficulty be brought under any system.

His views are illustrated by forty-two plates, chiefly from micro-photographs. These are of large size and beautifully executed. The first ten are of the normal kidney, to be used for comparison. One of the supposed advantages of this mode of illustration is that the reader can study and compare the plates as he would microscopic slides, as they are exact transcripts of nature. We wish, therefore, that the same power had always been employed in the ones which are thus to be used, instead of varying it, as has been done in many cases; thirty diameters to be compared with fifty, four hundred with four hundred and thirty or with two hundred and twenty diameters.

This certainly is the ideal method of illustration, and as marking progress thanks are due to Dr. Delafield for the great trouble he has been at in giving us this handsome book. But we feel in the present stage of the art that the average reader who has not had considerable experience with the microscope will fail to appreciate the differences which are intended to be conveyed here, and which, under the hand of a skilful draughtsman, would have more clearly presented the author's views.

— Dr. J. T. McCormac, writing to the *Medical News*, says that the old saying, that "there is nothing new under the sun," is beautifully illustrated by the latest of Dr. Brown-Sequard's "discoveries." For over twenty years, to the personal knowledge of the writer, and probably for as many centuries, the Chinese have used the testicles of the sea lion for the purpose of stimulating the organs of generation in man, and as a general nerve stimulant.

A great many sea lions are killed, chiefly for their oil; but the bristles, and penis with testicles, are sold to agents of the Chinese. The first are used for ornaments, but the last two articles are used by them as medicine. At times as many as one hundred and fifty are seen drying in the sun. When needed, a portion of a testicle is grated into a vessel, and an infusion is made, which is administered *pro re nata*.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 5, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 Washington Street, Boston, Mass.

PROPHYLAXIS OF TUBERCULOSIS.

Report of the Paris Commission. – Instructions to the Public. – The Discussion at the Academy of Medicine.

The Permanent Commission, appointed last year by the Congress for the Study of Tuberculosis, has just presented its report, through M. Villemin, Chairman. This report embodies certain instructions to the public, which the Commission deems of sufficient importance for general adoption. We can only summarize this report, a comparison of which with those issued in Berlin and New York, and previously referred to, offers interest.

Tuberculosis is, of all diseases, that which has the most victims, especially in the cities. More than one-fourth of the mortality of Paris, during the year 1884, was from tuberculosis in some of its forms.

Tuberculosis is a parasitic, virulent, contagious, transmissible disease, caused by Koch's bacillus. The microbe penetrates the organism by food, by air of respiration, and through the skin and mucous membranes by abrasions, excoriations, and divers ulcerations.

Certain diseases, as measles, chronic bronchitis, pneumonia; certain constitutional states due to diabetes, alcoholism, syphilis, predispose to tuberculosis.

The cause of tuberculosis being known, there is but little difficulty in preventing its dissemination and propagation, if proper prophylactic means are taken.

The parasite of tuberculosis may infect the milk, muscles, and blood of animals which serve for the food of man.

Raw meat, underdone meat, blood, may contain the living germ of tuberculosis, and should be interdicted. For the same reasons, milk should be boiled before being ingested. By reason of the dangers which attend the use of raw milk, the protection of young children, who are so susceptible to tuberculosis, should earnestly engage the attention of mothers and nurses. Lactation by a healthy woman is the ideal method. The tuberculous mother should be forbidden to nurse her infant, which should be confided to a healthy wet-nurse living in the country, or where the hygienic conditions are good. The risks of tuberculous contagion are less in the country than in the city. If nursing at the breast be impossible, and the infant is reared on cow's milk, the latter ought always to be boiled. Goat's or ass's milk is less objectionable, and may be given unboiled.

By reason of the dangers which attend the use of butchers' meat, which may come from animals that were tuberculous, though having every appearance of health, the public should insist that the inspection of all meats, as required by the law, should be rigorously enforced.

The only sure way of avoiding the dangers arising from meat derived from tuberculous animals, is to subject such meat to a thorough cooking, which shall include the entire substance in depth, as well as the surface; meats completely roasted, boiled, or broiled are alone safe.

As the germ of tuberculosis may be transmitted from the tuberculous to the healthy man, by sputa, pus, dried mucosities, clothing, or other objects impregnated with fine tuberculous particles, it is necessary for the public, in order to be protected against the contagion:

(1) To know that, the sputa of phthisical patients being the most formidable agents of the transmission of tuberculosis, there is danger in allowing these expectorated matters to be deposited on the ground, on carpets, on drapery, screens, towels, handkerchiefs, clothing, and bed linen.

(2) To be persuaded that the use of spittoons is obligatory on all phthisical patients everywhere. Spittoons should always be emptied into the fire and cleansed with boiling water. They should never be emptied on dung heaps, on garden soil, (where they may tubercularize fowl), nor into privies.

(3) To refrain from sleeping in the bed of a tuberculous patient; to remain as little as possible in a room occupied by such person. This caution is especially applicable to young children.

(4) To sequestrate from all places occupied by phthisical patients, individuals considered as predisposed to tuberculosis; children born of tuberculous parents, or that have lately had measles, small-pox, pneumonia, etc; all diabetic patients.

(5) To avoid using objects which a phthisical patient may have contaminated (garments, bed-clothing, toilet-implements, playthings, etc.) till after previous disinfection (in the hot-air stove, by boiling water, sulphur fumigations, etc.).

(6) To insist that the rooms of hotels, furnished houses, cottages occupied by phthisical patients at watering-places or winter stations, shall be equipped and tapestried in such a way that disinfection may be

easily and completely effected after the departure of each patient. It would be better that these apartments should have no hangings or tapestry, and that they should be whitewashed; the floors should be bare, either oiled or painted. Hotels and furnished cottages in which such hygienic precautions and measures of disinfection are taken should alone be patronized by the public.

At the meeting of the Academy of Medicine, August 6, 1889, this report was discussed. Dujardin-Beaumetz was in favor of suppressing entirely the sections pertaining to raw meat and raw milk. There is nothing that proves the possibility (in man at least) of the transmission of tuberculosis by butchers' meat. As for milk, if it be true that it may on certain occasions contain bacilli, we must not forget that in order that milk may be thus contaminated the cow must not only be tuberculous, but must also have tuberculous mammitis.

Germain Sée did not believe in the communication of tuberculosis by the air of respiration. The bacillus cannot live in the air; it never develops and multiplies outside of the organism of man or the animal; in the open air it dies rapidly, as, in order to live, it needs a temperature of 30° C. The matter of atmospheric contagion is a bugaboo, which has already wrought trouble in families by causing the poor consumptive to be treated like a leper — shunned and abandoned by his nearest relatives. It has been demonstrated experimentally, that air taken three or four yards from the bed of a consumptive patient does not contain a single bacillus; but if the air exhaled by a phthisical person is inoffensive, the sputa are not so, and too much pains cannot be taken to disinfect and destroy all expectorated matters.

With regard to the prohibition of meat and blood, it is a fact, said Professor Sée, that the blood is never virulent, and animal flesh, according to recent experiments (Nocard, of Alfort), far from containing bacilli, destroys them by the muscular juice which the flesh contains. Hence, there is no necessity, in order to destroy the bacillus, to boil meat to a pap, to forbid roast meat, or underdone meat, or even raw meat. If we were to hearken to the Commission, he thought we should be deprived of some of our best alimentary products, and nothing would be served on our tables that was not spoiled to the taste by over-cooking, as well as rendered more indigestible thereby.

With regard to the care that should be taken of those that were hereditarily predisposed to tuberculosis, he thought that excessive precaution was an evil; the best prophylactic is gymnastic exercises and hydrotherapy.

Professor Sée did not think persons especially liable to tuberculosis, who had been subject to colds, bronchitis, or who had had pneumonia, measles, whooping-cough, or small-pox. On the contrary, he had found such persons remarkably exempt from tubercular diseases.

TUBERCULOUS MEAT.

SIMULTANEOUSLY with the report of the Permanent Commission of the French Congress on Tuberculosis, we have before us a voluminous report from Glasgow,[1] giving the proceedings at trial, under petitions of the Glasgow local authority, against two butchers who exposed for sale, for human food, the carcasses of two tuberculous animals. Among those giving testimony at the trial we find the well-known names of Dr. J. B. Russell, Medical Officer of Health for Glasgow since 1872; Joseph Coats, pathologist to the Royal Infirmary of Glasgow, and Prof. J. McCall, Principal of the Glasgow Veterinary College. In addition, there were the medical officers for Edinburgh and Greenock, and for Leeds, Birmingham and Hull; three other veterinary pathologists besides McCall; and Mr. Mayland, as a bacteriologist and pathologist in addition to Dr. Coats. There were, in all, fifteen witnesses for the prosecution and nineteen for the defence. The conclusions of the French Congress, as well as of the Brussels Veterinary Congress of 1883, and of a Departmental Committee of the Privy Council, were frequently referred to in the course of the testimony.

The cases were test cases, brought to enable the medical officers of Glasgow to apply the same stringent standards as were already enforced in Edinburgh and Greenock.

The evidence showed that, in regard to one of the animals, "there were tubercles in the substance of the lungs themselves, in both the costal and pulmonary pleura, in the pleura connected with the diaphragm, and further in the cavity of the body enclosing the respiratory organs;" there was tubercular deposit in the lymphatics, and tubercular bacilli were found in the inguinal gland. In regard to the other, it was shown that there was active tuberculosis in the lungs and pleura, and bacilli were found in the prepectoral gland. The question before the court was, whether the meat of these animals after the carcasses had been "stripped" was "unfit for the food of man."

The prosecution laid down five propositions, and asked for conviction upon their acceptance by the court: (1) The disease called tuberculosis, whatever form it may assume, whether phthisis, or scrofula, or struma, is a widespread disease amongst animals and man, and to it may be attributed a large percentage of the deaths in the community, and a very large proportion of the ill health. (2) That the disease known as tuberculosis now, is identical in man and in the lower animals. (3) The disease is communicable from the lower animals to man, by, amongst other means, inhalation and ingestion. (4) The disease tuberculosis is due to the active presence of a specific organism known as the bacillus tuberculosis. (5) Given the signs of tuberculosis upon certain specific organs of an ani-

[1] Tuberculous Meat. Proceedings at Trial under Petitions, at the Instance of the Glasgow Local Authority, against Hugh Couper and Charles Moore, before Sheriff Berry, at Glasgow, on May 28, 29, 30, 31, and June 1 and 17, 1889. Interlocutors, June 20, 1889. Glasgow: Printed by William Hodge & Co. pp. 414.

mal, you may and ought reasonably to infer that the virus of the disease is in other portions of the carcass of the animal, where there may be no outward and visible signs to indicate its presence.

The defence held that: No one has ever yet heard of a case of tuberculosis contracted from the ingestion of tuberculous meat; but in the case of milk, the disease has been traced, and if in the latter, why not in the former; that cooking was a sufficient safeguard, and if people preferred to eat partially cooked meat, they should be allowed to take whatever infinitesimal risks might exist; that, even when the bacillus enters the alimentary canal, there must be a degenerated condition of the tissues before it can find lodgement and fructify; that to a healthy person, therefore, the danger is perfectly visionary; that the alimentary canal is the least favorable channel for entrance into the system; that the disease in these cases was so localized as not to affect the flesh in general; that, in any case, the danger to health and life must be extremely small, too small to justify the exclusion from the market or destruction of large amounts of good, wholesome food.

The prosecution pointed out the inherent difficulty of proving, as a matter of fact, and not merely as a matter of opinion, the actual communication of tuberculosis to human beings by the ingestion of the flesh of tuberculous animals; and adduced evidence that the flesh of animals affected with tuberculosis, more or less, and offered for sale for food in Glasgow, is one half per cent. in the year.

In summing up the evidence and the arguments, the court held that: Whether ingestion be or be not the commonest way in which tuberculosis is communicated, it must certainly be regarded as one mode of its communication; except on the footing that the meat was the medium of the transmission of the disease, it would be unnecessary and wasteful to exclude from the food-supply the carcasses of animals suffering from tuberculosis, however generalized and extensive; but the previously existent practice in Glasgow and elsewhere of condemning extensively diseased animals, clearly showed that the transmissibility of the disease by ingestion had long been recognized, and the evidence lead to the conclusion that it would not be proper to trust to cooking as a sufficient protection; that every animal suffering from tuberculosis, however limited in degree or apparently in locality, probably ought to be condemned, and that such condemnation would not cause a loss of food of more than one-quarter of one per cent; but, in the present instances, the disease, having extended to the lympathic glands, was undoubtedly generalized.

The number and character of the witnesses, the clearness of statement of the counsel, the respectability of the court and the Scotch reputation for shrewd, practical common sense, give the report and result of this trial a considerable interest, as bearing upon the present position of science and practice in regard to the questions involved. Should it ultimately appear, as we see by the published abstract of a paper, to be read at the approaching meeting of the Association of American Physicians, Dr. H. C. Ernst thinks he is in a position to prove, that the milk from a cow suffering from tuberculosis is dangerous as an article of food, no matter where the pathological change may be situated, and that Koch's limitation of the danger to tuberculosis of the lacteal tract was too restricted, then the position of those who condemn the meat, even of locally infected animals, would be greatly strengthened.

THE MODE OF ACTION OF HEART TONICS.

PROFESSOR STOKVIS, of Amsterdam, has recently performed some experiments to ascertain the mode of action of cardiac tonics. In order to do away with all external influences, he experimented with the heart of cold-blooded animals, isolated from the body of the animal, and traversed by an indifferent liquid rich in oxygen.

He observed that digitalis produces on the heart thus isolated an augmentation in the frequency and energy of the cardiac contractions; it acts on the vaso-motor centre, and on the muscular fibres of the small vessels which contract, giving rise to an augmentation of the blood pressure. He infers from these effects that digitalis is always indicated when the pulse is frequent, small, irregular, when there is accumulation of venous blood, and when diuresis is diminished.

Professor Stokvis has made experiments with other substances regarded as heart tonics, with these results:

Adonis vernalis and convallaria majalis have an action much less persistent than digitalis, and may also accumulate in the organism like the latter. On the other hand, strophanthus is more active than digitalis, but has no influence on the vaso-motor centre, and the augmentation of the blood pressure is due solely to its stimulant action on the heart.

As for sparteine, it diminishes the force of the heart, and does not act on the vaso-motor centre.

Caffeine possesses a very marked diuretic action; it acts in a special manner on the epithelial cells of the uriniferous tubes, and augments both the frequency of the pulse and the blood pressure.

ON HYPNOTISM AND SUGGESTION IN THE TREATMENT OF MENTAL DISEASES.

AT the recent Congress of Experimental Hypnotism, held in Paris, August 8–12, 1889, M. Aug. Voisin, of Paris, referee, spoke of the treatment of mental diseases by hypnotism. Till 1880, hypnotism in the insane was considered an impossibility. At this epoch M. Voisin succeeded in a case of acute mania; then he sought to hypnotize other insane patients, and succeeded in obtaining hypnosis in ten per cent. of the patients. He has applied hypnotism to combat the vices, the grovelling inclinations, the abuse of medi-

cines, certain defects of the intelligence, the neuralgias, the contractures, etc., in the insane.

Much time and patience, he says, are required; one must repeat ten and even twenty times the attempts. Lethargy or somnambalism must be obtained, but better the former. Let the patient sleep half an hour or an hour at the first *séance*, and do not commence suggestion until the second.

M. Voisin takes up but one delirious conception at a time, and lets the patient sleep a long time, even twenty-four hours. The "suggestion" must be uttered distinctly and imperiously. The patient must be disengaged from all external influences, then each hallucination must be combated successively; his delirium *must be worn out piecemeal*. Then the patient is persuaded that a cure is possible, and lastly this is affirmed.

The lunatic sometimes manifests bad temper when his hallucination is combated; it is then necessary to insist until his consent is obtained. The operator should be careful not to suggest illusions of any kind; he should give only good advice, counsel work, etc.

Voisin claims excellent results from this practice, in the troubles and hallucinations of the senses or of the general sensibility in dyschromatopsia, in anæsthesia and hyperæsthesia, in neuropathic paralysis and contractures, and in onanism. He claims, moreover, to have found hypnotism very efficacious as a means of moral discipline in degenerate and profoundly vicious children. He has observed relapses in a tenth of the cases, and has found it necessary frequently to renew the treatment.

At the same meeting, Dr. De Jong spoke of the value of hypnotism in melancholia. This is one of the psychoses most favorably influenced. He has also known hypnotic suggestion to cure agoraphobia, the fear of thunder, the "*folie de doute*," and writers' cramp!

MEDICAL NOTES.

— The 57th Annual Meeting of the British Medical Association was held from August 13th to 16th, at Leeds. The attendance was over 900. The address in Medicine was given by J. Hughlings Jackson; and that in Psychology by Sir James Crichton-Browne. The meeting was under the presidency of Mr. Wheelhouse, and it is said by our British contemporaries to have been one of the most successful ever held.

— The new building for Christ Hospital, in Palisade Avenue, Jersey City Heights, is now nearing completion. It will be finished in October, and will be opened and dedicated with interesting ceremonies. The new building is three stories high, built of red brick, with brown and gray stone trimmings. It is in the shape of a cross, and over the entrance is inscribed, "Christ Hospital, A. D., 1888. Erected in Memory of Richard Mason Abercrombie." The view to be had from the windows is beautiful, and all the rooms are commodious.

— The following call has been issued: "The members of the medical profession in Alabama, Georgia and Tennessee are requested to meet in Chattanooga on the third Tuesday in October, for the purpose of forming a Tri-State Medical Association. All will be admitted to the meeting of the Association, but the membership will be restricted to graduates of regular Medical Colleges in good standing."

This call is signed by committees from Jackson County, Alabama, Medical Society; Chattanooga, Tennessee, Medical Society; Cleveland, Tennessee, Medical Society; Cartersville, Georgia, Medical Society, and Dalton, Georgia, Medical Society.

— The *New York Medical Journal* says that some medical students have asked the Mayor of New York to allow them a certain number of condemned dogs from the pound, for experimental purposes; that functionary has duly considered the request, also the protest of a certain humane person who dreads the cruelty to which the dogs might be subjected by the students, and has come to the conclusion that he will allow the students a supply of dead dogs but no live ones. This generosity reminds our contemporary of Artemus Ward's, as exemplified in his answer to a person who had asked the privilege of seeing his show without paying: — "No, you can't go in without paying, but you can pay without going in."

One of the latest inventions in sanitation is machinery for personal washing, says the *Popular Science Monthly*. A French colonel, according to Mr. Edwin Chadwick, ascertained that he could wash his men with tepid water for a centime, or one-tenth of a penny a head, soap included. The man undresses, steps into a tray of water, and soaps himself, when a jet of tepid water is played upon him. He then dries and dresses himself in five minutes, against twenty minutes in the bath, and with five gallons of water against seventy in the usual bath. In Germany they have an arrangement under which half a million of soldiers are regularly washed. By an adaption of the apparatus to the use of schools, a child may be completely washed in three minutes.

BOSTON AND NEW ENGLAND.

— A reporter gained access to the Boston Dispensary, the other day, and witnessed the application of the "suspension treatment" to a friend of his, presumably for tabes dorsalis, and after describing the apparatus, announces that it was first introduced into this country six months ago, and was the invention of Dr. Sayer, a Russian!

— A correspondent sends the following prescription. It was presented at one of our local drug stores, a short time since:

> Bolsom kaparie.
> Cramatartæ spirits initre.
> sulphuratis zync and rose water.

There were no quantities affixed. The disease for which it was deemed a cure is obvious.

— Dr. J. B. Andrews, of Mary Fletcher Hospital, has been elected Instructor of Physiology in the winter course of the Medical department of the University of Vermont; Dr. Linsley, who has held the position, being obliged to resign on account of his engagements in New York.

— The resignation of Dr. Charles E. Woodbury as Superintendent of the Rhode Island Hospital will take effect September 1st. The directors of that institution have chosen as his successor, Dr. John M. Peters, of Syracuse, N. Y. Dr. Peters is a graduate of Harvard Medical School, and during the year and one-half previous to May 1st, acted as house-officer at the hospital.

— Dr. Robert T. Davis, of Fall River, has been selected by Governor Ames as the third member of the Metropolitan Drainage Commission; the other two members (who have been confirmed by the Executive Council) being Hosea Kingman and Tilly Haynes. Dr. Davis, in addition to considerable political experience, including among other service that as mayor of Fall River, state senator, and member of Congress, brings to the Board a good sanitary knowledge. He was at one time a member of the State Board of Health.

Miscellany.

PHENACETIN IN PERTUSSIS.

Dr. George C. Irwin, of Sabetha, Kansas, reports in the *Archives of Pediatrics*, August, 1889, a case of uncomplicated pertussis, with severe laryngeal spasms of hourly occurrence, in an infant aged three months, for which, after using atropia, antipyrin, quinine, and other remedies so often recommended for this disease, he gave phenacetin in one-half grain doses in ten drops of pure glycerine, which is a moderately good solvent, and was surprised to find that it immediately gave relief, so that the first night after using it every four hours the child obtained six and one-half hours' good rest, and there has been a steady and gradual improvement since.

TREATMENT OF UTERINE COUGH.

The *Revue Gén. de Clin. et de Ther.* of June 27th, states that the valerianate of quinine will be found most valuable in the treatment of uterine cough. Its beneficial action is ascribed to its antispasmodic properties, as the affection itself is of a reflex nature.

I.

℞ Valerianate of quinine . . . . . grs. xv.
Infusion of black coffee . . . . . f ℥ jv.
Simple syrup . . . . . f ℥ jss M.
Sig. — One, two or three large spoonfuls after meals.

II.

℞ Valerianate of quinine
Extract of quinquina . . . . . } s. a.
Divide into ten pills.
Sig. — One pill after each meal.

The drug may be prescribed either in solution or pill form, as above. If the former is used, the addition of an infusion of black coffee will be found valuable.— *Medical News.*

MEDICAL MINIMS AND SURGICAL SAWS.

The most effective instrument of medical surgery is the nail-brush.

The patient's interest in his own case is clinical; it is rarely pathogenetic, and never necroscopic.

A long prescription maketh no one fat but the druggist.

Better is aqua fortis with a ready stomach, than the best drug of the pharmacopœia and retching therewith.

Woman has some organs outside the pelvis.

Berlin makes a physician learned; Vienna skilful; the bedside wise.

The same channel brings their bread alike to the harlot and to the virtuous midwife.

The truly *necessary* calls upon a physician will about suffice to pay his tythes.

In the domestic republic the family physician is nominated by the husband, but confirmed in executive session by the wife.

The good medical Samaritan must needs look to it lest he be sued for the quality of his wine and oil, the speed of his beast, and the roominess of the quarters he provides in the inn. Albeit he gives of them all the best he has, he may find that the one who has most fallen among thieves is himself.

THE DIAGNOSIS AND THE TREATMENT OF ECTOPIC PREGNANCY.

The above subject is considered by Dr. H. T. Hanks in the *New York Post Graduate Journal*, for July, 1889; and, after reviewing his own cases, the writer reaches these conclusions:

(1) *Electricity.*— If the diagnosis is made during the first three months, and if the symptoms have been only the early or premonitory symptoms of rupture, use electricity.

(2) *Laparotomy.*— If the diagnosis is not made until the fourth month and the severe symptoms continue, do a laparotomy, and remove the sac and contents in the most approved manner.

(3) *Laparotomy.*— If a diagnosis is made at whatever stage of ectopic pregnancy, and if the symptoms are alarming, and undoubtedly due to rupture and loss of blood, do a laparotomy at the earliest possible moment consistent with the patient's ability to endure an operation.

(4) *Delay a laparotomy until the seventh month.*—If the diagnosis is made after the fifth month, and the symptoms are less and less severe, the fœtus undoubtedly not in the Fallopian tube, and if the patient is anxious to bear a living child, and you are prepared to watch the patient, and be ready to meet, by laparotomy, at a moment's notice, any emergency which may arise, then delay is justifiable until the child is viable, in order that a laparotomy may be performed with the possibility and probability of saving *both* mother and child.

Operate in best manner for removal of dead fœtus.— When the pregnancy has continued beyond the ninth month, and the fœtus is found to be dead, the *amount* and *character* of *general* and *local disturbance* occasioned by the dead fœtus must determine when an abdominal section should be made, other operations performed, and the offending body removed.

A CASE OF ARROW POISONING BY CURARE.

MR. JOSEPH WHITE described to the Nottingham Medico-Chirurgical Society, as we learn from the *Lancet*, the case of a servant girl aged twenty-three, who, while standing on a pair of steps dusting some shields, etc., on the walls of the hall, fell to the ground, and in her fall had her right arm pierced by the point of an Indian arrow, which was arranged point upward in a stand below. The arrow was withdrawn in two minutes, and the patient was seen within half an hour of the time of the accident. When seen, the patient was in a state of collapse, with slow, shallow, jerking respiration and very feeble circulation. As the wound was throughout its track covered with brown (apparently vegetable) substance, it and the surrounding tissues were immediately freely excised and stimulants administered. The breathing becoming rapidly more slow and feeble, and then ceasing, an interrupted galvanic current was passed through the diaphragm, and artificial respiration kept up for more than an hour, during which time the heart acted extremely feebly. In two hours from the occurrence of the accident, and when artificial respiration had been maintained for about an hour and a half, respiration gradually returned and the pulse improved, and in a short time the patient was able to take small quantities of fluid nourishment, and during the day she gradually revived. For three or four days the girl remained in a very feeble condition. She was drowsy and disinclined for any mental effort, had persistent loathing of food, nausea, and constant headache, and during this time there was a large flow of urine of low specific gravity (1008), showing traces of albumen, and on the third day very slightly bloody. There was no trace of sugar. The wound on the arm after excision rapidly got well. It was believed that the arrow had been poisoned with woorari (curare), which was shown by experiments of Claude Bernard, Sibson, and others, to produce effects of a strikingly similar kind to those observed in this case.

TWO CASES OF ANTIFEBRIN POISONING.

THE *Medical News* has collated two recent cases of antifebrin poisoning. The first case, reported in the *Münch med. Wochenschrift*, No. 19, 1889, was that of a man, aged thirty-four, who fancied he had symptoms of fever, and procured from a druggist six antifebrin powders, of fifteen and one-half grains each. Returning home he took one powder every hour until five had been taken, beginning at 8.30 P. M., the total amount being seventy-seven grains. At four o'clock in the morning the patient was seized with violent diarrhœa. At about noon his appearance was as follows: Conjunctiva, lips and mucous membrane of mouth were blue; pulse small, but of normal frequence; heart normal. The urine gave aniline reaction. Extreme weakness, dizziness and chills; temperature 99° F.; evening, 101° F. Temperature on the following day, morning, 95° F.; evening, 100° F. The diarrhœa persisted for several days, the stools being quite watery and of a grayish black color. The patient suffered from loss of appetite, and recovered but slowly. In ten days he was able to be about again.

The second was reported in the *Wiener med. Presse*, No. 16, 1889, and has the following history: the patient was a girl, who, to relieve an attack of hemicrania, had taken sixty-two grains of antifebrin. Immediately after taken the dose she experienced nausea, eructations, and later, pain in the region of the stomach, and copious vomiting of a greenish watery fluid. These symptoms were followed by cyanosis, at first only of the lips, later of the entire face, hands and feet, whilst the skin of the body was pale and very cold. Pulse weak, almost imperceptible, but frequent, 140 pulsations to the minute; respirations shallow and rapid; the patient almost entirely unconscious. Later, symptoms of cerebral irritation manifested themselves; enlargement of the pupils, muscular twitchings of the face, gritting of teeth, rigidity of the extremities, and delirium. The patient then sank into a deep coma, from which she awoke in three hours.

Eight hours after the poisoning her senses fully returned, pulse eighty-four, and fairly strong; respirations normal, temperature somewhat sub-normal. Patient complained of pain in the stomach, and dizziness. Cyanosis disappeared in twenty-four hours. In two days the patient was able to leave her bed.

Correspondence.

EFFICACIOUSNESS OF THE ELIXIR VITÆ.

BOSTON, September 2, 1889.

MR. EDITOR, — A merry pal of the writer, who comes directly from the headquarters of the elixir vitæ, quotes the following tidbit from *Figaro:*

An aged *viveur*, upon the point of espousing a young and pretty girl, consults the inventor of this popular brew, with a view of obtaining a renewal of youth.

"Mais c'est bien facile, monsieur." The aged scientist, turning to his assistant: "Apportez moi un lapin seulment."

"Je ne veux pas de lapin," replies the to-be husband. "I must have the glands of some more noble animal, — a lion, *par example*, or, at any rate, a bull."

"Allez chercher le taureau!" And the injections were skilfully and quickly given.

Three months later the couple meet again in the street. "Eh bien, monsieur; et votre mariage?"

The seeker for youthful virility says not a word, but, removing his hat, exhibits a pair of small but flourishing horns! SENEX.

PARIS LETTER.

THE PARIS INTERNATIONAL CONGRESS OF THERAPEUTICS AND MATERIA MEDICA.

PARIS, August 16, 1889.

MR. EDITOR, — An International Congress of Therapeutics and Materia Medica is so unusual an event, that a few lines concerning it may interest the readers of the Journal, of whom I suppose some have remained in America, notwithstanding the fact that one meets here more medical acquaintances and more medical fellow-countrymen than at home.

This congress met in Paris during August, and was the first of its kind which has ever been held. It has awakened the interest of a large number of medical men, of whom more than five hundred were inscribed as members just before the congress opened.

The meetings continued through three days, with long sessions in both morning and afternoon. The morning sessions were in sections, — one devoted to therapeutics, the other to materia medica. The afternoon meeting had

a more general character, and included both sections of the congress. The excellent arrangement of all that has been presented at the meetings was a characteristic feature. On the morning of the first day, only twenty minutes were required to transact the general business of the congress and begin its work.

The length of the communications to be presented was limited to ten minutes each, and irrelevant remarks were skilfully cut short. In this way it was possible to have a considerable number of communications presented, and then discussion was full of life and interest.

Socially, the congress was entertained by Professor Dujardin-Beaumetz and his wife at a brilliant reception at their house: it was much enjoyed by a large number of those who came to the congress. Another delightful evening was passed at a banquet in the marvellous Eiffel tower in the Exhibition grounds. After the dinner, through the kindness of M. Eiffel, an ascent was made to the top of this most wonderful structure. The view of the illuminated carpet a thousand feet below, including the Exhibition grounds and Paris, was a very beautiful sight.

From a medical standpoint the congress was full of interest; and, besides the value which the communications will have when published, there will remain the encouragement and enthusiasm which such a gathering imparts to those who have shared its activity and enjoyed the pleasure and profit of acquaintance and discussion. Further, it will develop a more comprehensive conception of the questions involved in the treatment of disease. The enthusiast for some special form of relief for a given disease may learn at such a gathering that other methods have been equally successful; he may also be lifted to a point where he can appreciate the true relation borne by his observations to the general principles which underlie the treatment of that disease. The opportunity to observe how the same problem affects minds of medical men of various nationalities is most suggestive and instructive, and the whole question of treatment, as well as the special topic under discussion, is presented to the listener with a sweep and breadth not easily attained in any other way. Frequent meetings of those who are active in this department of knowledge can be made of much service; everything which will assist medical men to study the problem of giving relief to their patients from the widest possible standpoint will promote the simplification and advance of therapeutics.

As an indication of what will be accomplished at future meetings the result of this congress is full of promise. There will be a second meeting of this congress two years hence in Brussels.

F. H. W.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 24, 1889.

Cities.	Estimated Population for 1889.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

SOCIETY NOTICES.

ASSOCIATION OF AMERICAN PHYSICIANS. — Programme of the Fourth Annual Meeting, to be held in the Medical Museum and Library, corner of Seventh and B Streets, Washington, D. C., September 18th, 19th and 20th, 1889.

Wednesday, September 18th. — Morning Session, 10 A. M. (1) The President's Inaugural Address. Francis Minot, Boston. (2) General Business. (3) The Early Stage of General Paralysis. C. F. Folsom, Boston. (4) Tetany. James Stewart, Montreal. (5) Tetany and a New Theory of its Pathology. John T. Carpenter, Pottsville.

Afternoon Session, 2.30 P. M. (6) Thrombosis of the Cerebral Sinuses and Veins. A. B. Ball, New York. (7) Chylous Effusions into Serous Cavities. S. C. Busey, Washington. (8) Substitutes for Opium in Chronic Diseases. J. F. A. Adams, Pittsfield. (9) Remarkable Case of Slow Pulse. D. W. Prentiss, Washington.

Thursday, September 19th. — Morning Session, 10 A. M. (10) Discussion on the Relation between Chlorosis, Simple Anæmia, and Pernicious Anæmia, including Leucocythæmia and Hodgkins' Disease. Referee, Frederick P. Henry, Philadelphia; Co-Referee, F. Forchheimer, Cincinnati. (11) Primary Cancer of the Duodenum. E. N. Whittier, Boston. (12) Primary Cancer of the Gall Bladder and Ducts. John H. Musser, Philadelphia. (13) Gastric Neurasthenia. G. M. Garland, Boston

Afternoon Session, 2.30 P. M. (14) Specimens from two Cases of Cretinism. W. F. Whitney, Boston. (15) The Anatomical and Physiological Relations of Lesions of the Heart and Kidneys. H. F. Formad, Philadelphia. (16) The Contagium of Diphtheria. P. Gervais Robinson, St. Louis. (17) A Supplementary Inquiry into the Frequency with which Lead is found in the Urine. James J. Putnam, Boston.

Friday, September 20th. — Morning Session, 10 A. M. (18) General Business. Report on Nomination of Officers and Members. (19) Discussion on the Relations of Rheumatism to Rheumatoid Arthritis; Referee, William Osler, Baltimore; Co-Referee, Morris Longstreth, Philadelphia. (20) How Far may a Cow be Tuberculous before the Milk becomes Dangerous as a Food Supply? Harold C. Ernst. Jamaica Plain. (21) The Bacillus Tuberculosis. J. T. Whittaker, Cincinnati. (22) Hot Air Inhalations in Tuberculosis. E. L. Trudeau, Saranac Lake. (23) Concluding Business.

On Thursday evening it is proposed that the Association shall have an Annual Dinner. Definite information concerning this dinner will be given at the morning session of Wednesday.

AMERICAN GYNECOLOGICAL SOCIETY. — Programme of the Fourteenth Annual Meeting, to be held in the Massachusetts Institute of Technology, Boylston Street, Boston, September 17, 18, and 19, 1889. Physicians are cordially invited to be present.

First Day. — Morning Session at 10 o'clock. Roll-call, Reception of Guests, etc. Address of Welcome. Dr. J. P. Reynolds, Boston. (1) A Case of Interstitial Pregnancy — Rupture of the Uterus and Laparotomy. Dr. R. S. Sutton, Pittsburg. (2) The Use and Abuse of Antiseptic Injections in Obstetric Practice. Dr. H. J. Garrigues, New York. Discussion to be opened by Dr. Fordyce Barker. (3) A Digest of Twenty Years' Experience in the Treatment of Cancer of the Uterus by Galvano-Cautery. Dr. John Byrne, Brooklyn. Discussion to be opened by Dr. Reeves Jackson. Afternoon Session at 3 o'clock. (4) The Nature and Limitation of Operative Treatment for Uterine Fibroids. Dr. P. F. Mundé, New York. (5) The Diagnosis and Treatment of Fibroid Tumors. Dr. W. Gill Wylie, New York. The discussion of these two papers will be opened by Dr. T. A. Reamy, Cincinnati. (6) A Case of Sloughing Intra-Uterine Fibroid. Dr. E. Van de Warker, Syracuse. Discussion to be opened by Dr. S. C. Gordon.

Second Day — Morning Session at 10 o'clock. (7) A Case of Abdominal Lipoma Simulating Ovarian Tumor. Dr. Reeves Jackson, Chicago. Discussion to be opened by Dr. Wm. T. Howard. (8) The President's Address. Dr. H. P. C. Wilson, Baltimore. (9) Electro-Therapeutics in Gynecology. Dr. G. Apostoli, Paris. Discussion to be opened by Dr. A. J. C. Skene. (10) Death from Visceral Lesions following Ovariotomy. Dr. H. C. Coe, New York. Discussion to be opened by Dr. H. Marion-Sims. Afternoon Session at 3 o'clock. (11) Renel Disease, caused by the Disease of the Pelvic Viscera. Dr. George J. Engelmann, St. Louis. Discussion to be opened by Dr. H. J. Kelley. (12) Pelvic Congestions *vs.* Pelvic Inflammations. Dr. S. C. Gordon, Portland. Discussion to be opened by Dr. T. A. Emmet. (13) The Relation of Uterine Retro-Deviation to Pregnancy. Dr. A. Martin, Berlin. Discussion to be opened by Dr. P. F. Mundé. (14) Nephro-Lithotomy. Dr. James R. Chadwick, Boston. Discussion to be opened by Dr. C. C. Lee. Evening Session at 8.30 o'clock. Business Meeting with closed doors.

Third Day. — Morning Session at 10 o'clock. (15) Results of Repression of Menstruation, Dr. E. C. Gehrung, St. Louis. Discussion to be opened by Dr. E. W. Jenks. (16) Intermediate Trachelorraphy, Dr. H. J. Boldt, New York. Discussion to be opened by Dr. Bache Emmet. (17) A Contribution to the Clinical History of Cystic Degeneration of the Ovaries, — with a Report of Cases and Specimens, Dr. R. B. Maury, Memphis. Discussion to be opened by Dr. W. M. Polk. (18) Partial Rotation of the Ovum in early Pregnancy as a Cause of Placenta Praevia. Suggested by two cases in Practice, Dr. E. W. Sawyer, Chicago. Discussion opened by Dr. A. F. A. King. (19) The Protective Influence of Vaccination during the Intra-Uterine Existence of the Fetus, Dr. C. Kollock, Cheraw, S. C. Afternoon Session at 3 o'clock. (20) The Value of Laparotomy in the Diagnosis and Treatment of Minor Forms of Intra-Abdominal and Intra-Pelvic Disease, Dr. T. A. Ashby. Baltimore. Discussion to be opened by Dr. A. W. Johnstone, Kentucky. (21) A Brief Report of my own Abdominal work, for the year ending September 1, 1889, Dr. R. S. Sutton, Pittsburg. Discussion opened by Dr. E. C. Dudley. (22) The Surgical Treatment of Posterior Displacement of the Uterus. Dr. W. M. Polk, New York. Discussion to be opened by Dr. W. M. Baker. (23) The Effect of Ergot upon the Parturient Uterus, Dr. John Goodman, Louisville, Ky. (24) In Memoriam. — Dr. J. B. Hunter, New York. Dr. H. C. Coe, New York. (25) In Memoriam. — Dr. Ellwood Wilson, Philadelphia. W. H. Parish, Philadelphia.

OBITUARY. EDWARD G. UFFORD, M.D., M.M.S.S.

Dr. Edward G. Ufford, who was nearly eighty-eight years old, died in his home in Agawam, August 25th. He was born in East Windsor, Conn. in November, 1801. He was a graduate of the Yale Medical School, in 1845, and began practice in West Suffield, since then having practiced in South Hadley, West Springfield, and Agawam. For years he had been a member of the Hampden County Medical Society, and was formerly president of the Hampshire. He lived in South Hadley twenty-two years, and was one of the original corporators of the Seminary. He was one of the oldest Masons in the Connecticut Valley, having joined the order in 1825.

PARTIAL TENOTOMIES IN CASES OF NEURASTHENIA, WITH INSUFFICIENCIES OF THE OCULAR MUSCLES.[1]

BY MYLES STANDISH, M.D.,
Ophthalmic Surgeon, Carney Hospital; Assistant Ophthalmic Surgeon, Massachusetts Charitable Eye and Ear Infirmary; etc.

THE ordinary symptoms of an error of refraction are well known, and are grouped under the descriptive title of Asthenopia; they consist of blurring of print, smarting of the lids, pain in the eyes and orbits, a heavy, dull pain in the temples or over the brows, and are often accompanied by occasional prostrating sick-headaches. All of these symptoms are aggravated upon any attempt to do near work, and some are relieved by the cessation of such work. There is no mistaking the cause of such a group of symptoms. The act of accommodation is evidently the source of the difficulty.

In normal eyes asthenopia is never felt until the accommodation has been sufficiently lost by the natural course of events to make near work difficult. In the hypermetropic eye (the short eye), on the contrary, asthenopia may appear very early in life. We do not have to search far to find a reason for this. Such a short eye, in order to focus a picture of a near object upon its retina, must do all the work that the normal eye does, plus the amount of its error. Moreover, such an eye must accommodate in order to see distant objects distinctly. Hence the constant strain and consequent fatigue. Astigmatism also is a common source of asthenopia, the cause of the nervous disturbance being, in this case, not so much due to the amount of labor put upon the ciliary muscle, as to the character of the work.

In an ordinary case of asthenopia, with all the symptoms present, the diagnosis, as I have said, is easy; but when the headache becomes very prominent, and the other symptoms are very slightly felt, or are not present at all, and especially when the headache does not appear until some hours after the use of the eyes, which has originated the nervous disturbance, then the diagnosis is not so apparent. To this class belong the large majority of school-children who have violent sick-headaches at frequent intervals; the many professional men who find it necessary to drop all work, and go off on short vacations every few months, and who return from such short trips with an improvement in mental and physical conditions which seems out of all proportion to the length of the vacation. To this class also belongs the business-man who spends his Sundays reading books and newspapers, and who invariably has a headache Monday morning. Herein lies the value of the change of scene, so advantageously prescribed by physicians in cases of physical depression of obscure origin. I believe that mere change of scene never improved a man who habitually lead an out-of-door life.

As I have implied above, refractive headaches bring in their train great impairment of mental and physical vigor. The dull, heavy pain in the head, accompanied as it generally is by a constant sense of fulness, is, in itself, very depressing; and when to this is added the occasional sick-headache, the result is a feeling of lassitude which is never absent so long as the use of the eyes is continually adding to that load already too great for the nervous system to carry.

Headaches and neurasthenic conditions are often much mitigated by the correction of errors of refraction when the starting-point of the reflex process is not in the eyes, but in the digestive or reproductive tract. In these cases the relief from the additional nervous irritation, caused by the strain upon the ciliary muscle and its auxiliaries, will reduce the severity of an habitually prostrating sick-headache to a so much milder form of cephalgia that the patient can go about and attend to his duties. The relief from the physical depression consequent upon such repeated prostrations may go far toward making successful the treatment of the original cause possible.

The treatment of an error of refraction is, of course, to place before the eye such a lens as will enable it to do its work with no more labor than would be required by a normal eye. The effect of such a lens is often marvellous. As soon as the eyes become accustomed to the new conditions, the headaches disappear entirely, together with irritability, choreic-like movements of the hands or head, and many obscure sensations and pains, previously referred to various causes. The patient, from being very nearly an invalid, is transformed into a well man, and is enabled to do his daily task with but a tithe of the accustomed fatigue. He is enabled to go to the theatre without paying the penalty of a headache the following morning, although the headache had always been attributed to the bad air of the theatre. He finds that he can do with impunity many other things which before always exhausted him, such as travelling on the railroad, visiting picture-galleries, etc. In short, he finds his general vigor and health much improved. In order to do away with the refractive strain in these neurasthenic cases, it is absolutely necessary that the correction of the error should be perfect, and that the lenses should be set in the frames with mathematical accuracy. If an incorrect lens is prescribed, or a cylindrical lens is set so that the axis is not correct, we have created an artificial astigmatism which is, when the glasses are worn for any length of time, as disastrous as the original error; although I have seen an incorrect lens give relief, apparently through doing away with the accustomed form of irritation, and to continue to so give relief until the cumulative effect of the fatigue from the new source of error was sufficient to develop the whole train of symptoms anew.

There is a certain class of cases in which the use of the eyes seems to stand as the direct cause of extraordinarily severe headaches, frequently accompanied by a condition of nervous prostration which utterly unfits its victims for the duties of life, yet when the errors of refraction are corrected only partial relief is obtained, and that not enough to be of material benefit. The direct relationship between the use of the eyes for near work and the most tremendous outbreaks of cephalgia and general nervous disturbance would seem to point to the eyes as in some way the direct precipitating cause, yet, as I have said, correction of refraction in the most careful manner utterly fails to give the relief we expect.

This class of cases is explained of late by attributing the cause to eye strain arising from an insufficiency of one or more of the recti muscles. This explanation has a *priori*, many arguments in its favor. It is but

[1] Read at the meeting of the American Ophthalmological Society, July, 1889, to which is added a few introductory remarks.

natural to suppose that in the case of any abnormality in the strength of the recti muscles there should be as much difficulty and fatigue experienced in maintaining binocular vision as there is in keeping the eyes constantly accommodated for distant vision in an error of refraction. The ciliary muscle and the recti muscles have to a great extent the same nerve supply, and it would seem that a reflex irritation would be as easily obtained from one source as the other. The confusing effect of slight diplopia associated as it is with ocular vertigo is well known.

Although this source of reflex irritation would seem so probable but very little has been done by ophthalmologists for the treatment of these difficiencies of the ocular muscles. An occasional pair of prisms has been ordered and their continual use has generally proved unsatisfactory, or at rare intervals a tenotomy of the overbalancing muscle has been performed. As a rule, however, no treatment for the inequality of the muscular balance has been attempted. Within a few years Dr. G. T. Stevens has proposed that as prisms did not accomplish the hoped for result in these cases, it was logical and proper to adopt operative interference and proposed an operation similar in character and method to a strabismus operation with the exception that the tendon of the overbalancing muscle was only partially severed from the globe, and the portion cut was only the central portion of the insertion, leaving the outer edges of the tendon intact.

The results obtained by this operation have been loudly extolled by Dr. Stevens and a few enthusiastic followers. It has been claimed by them that the eye strain in cases of illy balanced ocular muscles was responsible to a very large extent for all varieties of functional nervous disturbance. Not only were severe headaches and neurasthenia cured by this operation, but also neuralgia, chorea, epilepsy, and insanity. One writer in a recently published work on nervous diseases goes so far as to credit this operation with the cure of a case of chronic dyspepsia. The extravagance of these claims has undoubtedly prejudiced many gentlemen against the operation, and as a result, this method of treatment has not been generally accepted. Many have urged theoretical reasons why this particular form of operation should not accomplish the mechanical result desired, but as yet very few have actually tried the operation and reported the results.

In this state of affairs the question can only be settled by the public record of the experiences of different operators, and that is my reason for reporting this short series of cases.

With cases of chorea, epilepsy, insanity, dyspepsia, etc., I have had no experience. My patients have all been persons invalided by constant and severe headache, accompanied by a more or less neurasthenic condition which has utterly incapacitated them for their duties in life. The condition of such patients is truly deplorable, the victims of a constant dragging headache which increases to intolerable torture if they stir abroad or use their eyes for reading or any near work at home. They retire at night greatly fatigued, and arise in the morning with an aching head and burning eyes. This condition of affairs goes on for years, and the patient becomes a petulant, peevish, suffering invalid. Every practitioner of medicine has sooner or later found himself utterly helpless in the face of such a situation, and if it is possible by the relief of the strain caused by unbalanced ocular muscles to so lighten the load of nervous irritation, under which the patient is struggling, as to give him a practical cure of his asthenopia and neurasthenia, it is a possibility that should be thoroughly investigated.

It is true that very many such cases are entirely cured by the proper correction of errors of refraction, but a certain proportion of cases are relieved only for a short time by the lenses, and if tested will be found to have marked ocular insufficiencies.

The methods of examination as yet devised for the examination of the recti muscles are rather crude and inaccurate. The methods are two: —

First. In examining for the condition of the internal and external recti, for instance, a vertical diplopia is artificially produced by placing a prism before one eye with its base up. A lighted candle is placed at twenty feet in a darkened room. Then if one image of the candle flame is directly over the other the muscles are said to balance, but if there is a lateral displacement there is said to be an insufficiency. A similar test with a prism base in gives the balance of the superior and inferior recti. The measure of the amount of the insufficiency is obtained by placing prisms with their bases at right angles to that of the prism producing the diplopia, and recording the number of degrees required to place one image over the other. The variation at successive examinations in the number of degrees required to make the diplopia vertical in this test is sometimes very great. This is no doubt partly due to inherent difficulties in the method of examination which produce faulty observations, but I am sure that it is to a greater extent due to the physical condition of the patient at the time of the examination. If fatigued and exhausted a greater amount of insufficiency will be manifested than if the head is clear and the physical condition good.

Second. The practical strength of the muscles to fuse diplopic images into one, when such images are artificially produced, by placing a prism before the eyes with the base up or down, or in or out.

Theoretically one would suppose that these two tests would supplement and confirm each other, but practically I have often found this not to be the case at any single sitting. In fact, the results of these examinations of the ocular muscles are often exceedingly confusing, and vary greatly from day to day. It is customary to explain this variation by saying that the patient acquires the trick, after a while, of using his muscles under these new conditions, and so the different results are simply a record of the proficiency acquired in this new form of gymnastics. This explanation is to a certain extent true, and accounts, no doubt, for the much higher result obtained by the second method of examination after it had been repeated several times. It fails, however, to explain all the variations obtained, especially the results obtained by the first method of examination.

Recognizing the difficulties of accurate diagnosis by these methods of examination, it has been my practice to order prisms with the bases in the proper direction, to alleviate any strain that might be present from the supposed insufficiency as shown by these tests; to have them worn continuously for a longer or shorter period and see if any alleviation of the symptoms followed. I have a number of times confirmed myself

in my opinion by reversing the prisms, and finding that with this change the symptoms were aggravated.

With these introductory remarks I will now report five cases which I have abstracted from my records, and which constitute the entire number of such cases upon which I have operated.

Case 1. First seen by me August 11, 1887. B. H. R., clergyman, thirty-one years of age. A man of healthy appearance and robust stature. Has had asthenopia for six or seven years and has been treated by several gentlemen distinguished in the profession. Glasses, Dyer's method of progressive use of eyes, etc., have been prescribed without relief. The last two years the headache from the use of eyes has increased so that he has been obliged to give up all reading, and now the least excitement prostrates him with a headache. He cannot go down town, ride in the horse cars or make a social call, except in the dark, without precipitating a violent headache. Has been obliged to give up his duties on account of his infirmity, and for eighteen months has been almost an invalid. Cannot read over two pages without being obliged to stop on account of the pain. V. O. U. $\frac{12}{x}$. Ophthalmoscopic examination entirely negative. Overcame prisms today when looking at a lighted candle at a distance of twenty feet, four degrees with the base up or down — eight degrees with the base in, and twenty-five degrees with the base out.

Græfe's vertical diplopia test, with same object and distance, showed a state of muscular equilibrium. In a state of accommodation when one or the other of the eyes is covered, it apparently converges a little. On August 22d, after a week's use of a solution of atropine and cocaine in each eye, there appeared a hypermetropia of 0.50 Diopters in each eye; but the muscles overcame prisms only to the following extent when tested as before, — three degrees base up or down, six degrees base in, twelve degrees base out. Vertical diplopia test, as before, requires three degrees, base out, to place one image over the other. The inconsistency of this examination is obvious. If the ability of the muscle to overcome prisms is of any value as measuring the strength of the muscles, the above examination shows an insufficiency of the internal recti. If, on the contrary, the Græfe vertical diplopia test is of any value when applied as above, then there is an insufficiency of the external recti.

These examinations were repeated at intervals of four or five days until October 3d. The results, with regard to the ability to overcome prisms, was not found to vary much as to the vertical muscles, but the lateral muscles varied very considerably. When the base of the prism was placed toward the nose, the eye could fuse the images some days with eight degrees before one eye, another day three degrees would give permanent diplopia. With the base turned outward, the variation ran from twelve degrees to twenty-one degrees.

The vertical diplopia test, however, remained pretty nearly constant, requiring four degrees to five degrees base out, to place one image over the other. On October 3d, prisms were ordered two degrees base out, before each eye for constant use. October 22d, the patient reports that his eyes feel much better. Has left off his blue glasses which he had worn for eighteen months, and wears only the prisms without experiencing any photophobia. Has read an hour at a time. Has considerable headache still. I then reversed the prisms, placing their bases in, and on November 14th he reports that his eyes have been extremely painful. Has not been able to read any; headaches have returned with redoubled violence, and is obliged to lie down in a darkened room most of the time. The ability of the muscles to overcome prisms, when tested under these conditions, did not seem to stand in any relationship to the manner in which the prisms were worn, as for instance, when the prisms had been worn base in, on one occasion, the eyes overcame twenty-one degrees base out, and on another, twelve degrees, exactly as happened when the prisms were worn with their bases out. On the other hand, during this period if tested by the vertical diplopia test, the equilibrium was found to be perfect, which would seem to show that the added muscular exertion required to overcome the prisms worn (four degrees bases in), continued after they were removed, and exactly counteracted the natural insufficiency of the externi. The prisms were replaced with their bases out for distant use; and I ordered +0.50 D. combined with prism one degree base out, O. U. for near use.

With these glasses his headaches were much relieved. He was able to read to a limited extent, and could go about without the great fatigue or the neurasthenic symptoms which of late had attended all exertion. The eyes were examined from time to time after the prisms had been replaced with their bases out, with somewhat varying results as to ability to overcome prisms, but with an average about as follows, — three degrees up or down, eight degrees base in, and twenty-one degrees base out. Such a condition of the muscles as the above average would indicate is about the normal standard, I believe, except, perhaps, that twenty-one degrees is rather low for the limit of power of the internal rectus. The Græfe test required five degrees base out for vertical images. This latter test, together with the fact, that, if he omitted wearing his glasses for several hours, he invariably had a headache, determined me in my diagnosis of an insufficiency of the external recti. A partial tenotomy of the tendon of the internal rectus of one eye was proposed with the idea of restoring the muscular equilibrium.

The operation was promptly accepted; and on May 21, 1888, Dr. W. D. Hall being present, I cut about three millimetres of the centre of the tendon of the left internal rectus at its point of insertion. Two days later the patient reported that he had omitted the prisms since the operation, and that his head had not felt so well for six or seven years. Has walked two miles to my office without fatigue. Felt like a new man. Had tried to read with his prisms, but found that they made his eyes water and that he could read quite well without them, Overcame prisms four degrees base up or down, — nine degree base in, and nineteen degrees base out. Vertical diplopia test showed an equilibrium.

On July 6th, reports that several weeks ago he resumed his clerical duties and could do them without fatigue. Has resumed the use of prisms for reading, otherwise goes without them. Can read two or three newspapers through without fatigue. Reads several hours daily. On December 11th, I found that one degree base out was necessary for equilibrium with the vertical diplopia test at a distance of twenty feet. This condition has remained up to the present time, and on May 8, 1889, the gentleman says that he

never has headaches, that while his eyes do not admit of constant near work without fatigue, he is able to do all his work and some collateral reading. This report only lacks a few days of a year from the date of the operation, during which period he has had absolutely no treatment.

I have reported this case somewhat fully, in order to illustrate the difficulties of an accurate diagnosis, but the remaining four cases I will report in a somewhat briefer form.

CASE II. M. M., female, aged forty-two, teacher by occupation. She was first seen by me in June, 1887, complaining of asthenopia. Manifest hypermetropia found of 0.75 D. For reading, found that 2 00. D was necessary to give comfort. I ordered these glasses. The patient returned to me in May and June, 1888, complaining that she could only do her work with the greatest difficulty, on account of the pain in the head and eyes, and that the smarting of the lids was something extreme; and, as there was a distinct conjunctivitis, treatment by astringents was instituted, but this failed to give relief. The eyes were examined under homatropine, and hypermetropia of 2.00. D. O. U. found. The muscles overcame prisms two degrees base up or down, three degrees base in, and twenty-one degrees base out. Vertical diplopia test, at twenty feet, required two degrees base out. Ordered more persistent use of glasses and continual treatment of lids.

Although not teaching at this time, the patient's condition became gradually worse. Head ached most of the time. Pain in the eyes always present. Complained greatly of many rather fugitive pains. Was always greatly fatigued, and incapacitated from doing even her household duties. At my suggestion she was examined by her physician, who reported that the only cause he could find for her condition was overwork.

Her eyes were examined from time to time, and the ability to overcome prisms was found to be as follows: two degrees base up or down, three degrees base in, and twenty-five degrees base out. This condition remained pretty constant during the four months from June to November. The amount required to place one image over the other in the vertical diplopia test varied from two degrees to five degrees base out.

As the patient was now unable to attend to her duties, and seemed to be rapidly descending into a condition of nervous prostration, a partial tenotomy was advised and accepted. The operation was done November 13, 1888.

The operation was partial tenotomy of the internal rectus of the right eye. The insertion of the tendon was severed, so that the merest shred was left. When the operation was finished the divergence was quite marked, and diplopia was present. Eight hours after the operation, the visible divergence still persisting, and as the patient said all objects "looked funny," I thought best to approximate the edges of the cut in the tendon by a suture that was drawn up until I could see no divergence.

The operation was followed by considerable relief of the general fatigue; could work about the house. Headaches much relieved. There was still some pain in the eyes, however.

Examinations for the two weeks after the operation showed an ability to overcome prisms of two degrees base up or down, five degrees base in, and twenty-one degrees base out. Graefe test for distance required a prism of three degrees base out.

This patient has been able to do her work since the operation without fatigue, and her general condition is much improved. There is still considerable complaint of the eyes, It seems to me probable that we should have had a better result if I had drawn my corrective stitch less tightly.

CASE III. Mrs. R. W. B., fifty-one years of age, was referred to me by Dr. E. H. Bigelow, of Framingham. She gave the following history at her first visit on August 3, 1888: "Four years ago had an illness which was marked by pain in the region of the heart and hyperæsthesia. Said to have been accompanied by marked dimness of vision. During the attack light and sounds were extremely annoying." Has never been well since. Has headache pretty much all the time. Headache severe enough to incapacitate her from doing anything, and much worse upon any attempt to do near work. There is a constant sense of fulness in the head, accompanied by a feeling of extreme lassitude. The eyes are sore and painful, and patient dreads to move them about. Has worn dark glasses for two years. Patient kept the eyes closed most of the time when talking, and when asked why she did this, said it relieved the distressed feeling. Sensation of fatigue in eyes present upon first awakening in the morning. The slightest excitement, or the shortest railroad journey, brings on a violent headache, that confines the patient to her room for several days.

Upon examination, the condition of the eyes was found to be as follows: V. O. U. $= \frac{14}{x}$ not improved by any lens The muscles overcame prisms of two degrees base up or down, seven degrees base in, and eight degrees base out. Graefe vertical diplopia test, with a candle at twelve feet in a darkened room, showed muscular equilibrium at twelve inches; the same test required five degrees base in to bring the images vertical.

I advised, for experiment, a prism of two degrees base in before each eye for constant use. On August 27th, the patient reported that the prisms had given much relief to the ocular symptoms, but that otherwise she was about the same. Muscle test at this visit showed a power to overcome prisms of two degrees base up or down, eleven degrees base in, and eight degrees base out. The vertical diplopia test required, at twelve feet, three degrees base in; and, at twelve inches, seven degrees base in.

The bases of the prisms were then reversed, and upon September 14th, the patient reported that all her symptoms were much worse, as indeed her excitable manner during her visit plainly showed. This excitable condition produced a somewhat startling change in the tests with the prisms; for that day she overcame three degrees base down, four degrees base up, seven degrees base in, and *twenty-eight* degrees base out. The vertical diplopia test at twelve feet as before, required six degrees base *out*. Nevertheless, a partial tenotomy of the external rectus of the left eye was proposed, which was subsequently accepted, and on October 13th, I operated on the external rectus of the left eye. Cocaine was used. I cut the central third of the insertion of the tendon which was rather broad. An hour subsequently to the operation the vertical diplopia test showed equilibrium of the muscles for distance.

On November 14th, the patient reported that for two weeks following the operation she had felt perfectly well. Could not remember feeling so well since a child. Had attended some private theatricals and gone about very considerably. Since then the use of the eyes for near work had given some discomfort, and if long continued was followed by severe headache. She considers herself well by comparison. Has no sense of fulness in the head. The weariness had disappeared. Does not dread to look at people or to move the eyes as formerly. The eyes are now rested in the morning. Has no headaches except upon long-continued near work.

Prism tests of the muscles showed ability to overcome three degrees base up or down, nine degrees base in, and twenty-eight degrees base out. The vertical diplopia test at twenty feet required three degrees base in. I prescribed prisms one degree base in, before each eye, for near work.

December 19th, patient reported as follows: Has been very well, much better than ever before. Does not feel absolutely strong, and has a feeling as if it would be possible to overwork herself, if she was not somewhat cautious.

In February I wrote to Dr. Bigelow a letter of inquiry, and received the following reply: "Mrs. B. is very much improved in her general health since your treatment of her eyes. She seems like another person now, as I meet her. She certainly appreciates highly the help you have given her."

CASE IV. Mr. W. B. N., twenty-seven years, student, married. Was first seen by me on September 22, 1888. Patient was a large, athletic-looking man, and in flesh and color appeared to be a well man. The history was, that ten years or more ago patient "broke down" during his college course; at this time he was troubled with occasional diplopia. Dr. Agnew was consulted in New York, and said that there was insufficiency of the interni; prescribed prisms, and hinted at a possible operation on the eye muscles. The prisms were worn a short time with relief, and were finally omitted on the advice of another eminent ophthalmologist. Within a few years his eyes had been examined under atropine, and Cyl. + 1. 00. D., axis vertical O. U., ordered for reading. Patient has had four years of nervous prostration. Has been better the last six months. Has used eyes more than usual of late. Still has many nervous symptoms, and is obliged to rest much, and to devote much time to sleep, if he would feel at all well. Two weeks ago he began to walk unsteadily. Saw double when he arose in the morning. Has been nauseated by this diplopia. Diplopia has continued of late for three-quarters of an hour after arising. Can ordinarily have diplopia or not at will. Of the false images in the morning, one was above the other, and some distance to one side. Diplopia crossed.

The power of the muscles to overcome prisms was as follows: one degree base down, four degrees base up, six degrees base in, and fifty degrees base out, This latter result was accomplished by blurring the image, and it is probable that the accommodation was exerted to its fullest extent in the attempt to overcome the prism. Graefe vertical diplopia test twelve feet, showed equilibrium of muscles.

After two days of complete rest the muscle tests were as follows: Overcame prisms, two degrees base up, two degrees base down, seven degrees base in, fifty-nine degrees base out. Graefe vertical diplopia test required five degrees base in, for equilibrium. Ordered prisms two degrees bases out for trial.

September 29th, patient reported that the glasses had nauseated him, and aggravated all his symptoms. The prisms were reversed, and on October 6th, the report was that the glasses had given relief to the eyes, but that other symptoms were the same.

After this, many variations of the prisms were tried, with bases up, down, etc., with rather indecisive results as to the vertical recti, but a pretty constant evidence of insufficiency of the internal recti, and on November 17th, I did a partial tenotomy of the external rectus of the left eye. The central transverse incision of the tendon was not over two millimetres. On November 28th, the patient's statement of his condition was, "Have had to go back to the two degree prisms bases in, but with them, am much better off than before with three degrees or four degrees."

On December 1st, I did a partial tenotomy on the external rectus of the right eye. This operation still left, when entirely well, an insufficiency of the internal recti; and although at first it apparently gave considerable relief, the patient has gradually fallen back into his previous condition.

An operation on one of the vertical muscles was not accepted; and on April 12th he wrote me in response to an inquiry: "I am somewhat dependent upon the cylindro-prismatic glasses; I still seem to have about six degrees of lateral insufficiency; health has been about as wretched as usual."

CASE V. — G. P. H., forty-four years, clergyman, married. Seen by me on November 17th, 1888, and gave the following history: First broke down five years ago. Is said to have had nervous prostration. His condition has varied from time to time, but of late has steadily grown worse. Cannot attend to his duties, cannot read, sleeps very poorly. Is troubled much by pain in the forehead and back of the neck. Has sensations of weakness. If he attempts any work, has a nervous feeling or thrilling, which alarms him and incapacitates him for proceeding. Has a constant feeling of fatigue in the head. Has had two attacks of vertigo, after straining his eyes, which entirely disappeared upon closing the eyes. When he first began to preach, stammered, and overcame the fault with difficulty.

V. O. U. $= \frac{20}{xv} +$ Vertical diplopia test, at twenty feet, required prism one degree base out, to place images vertical. Muscles overcame prisms of four degrees base up, three degrees base down, four degrees base in, twenty degrees base out. Ophthalmoscopic examination revealed nothing abnormal.

Has worn, by advice, + 60 inch lens O. U. for reading, for the last few months. Advised prisms two degrees base out for constant use, for diagnostic purposes.

The gentleman returned to me on December 1st, and said that he had been very much relieved by the glasses. Had used his eyes freely. Headaches and other pains very considerably diminished.

Graefe vertical diplopia test showed an insufficiency of six degrees of the externi; and the muscles overcame a prism of four degrees base up, three degrees base down, eight degrees base in, and sixteen degrees base out, showing once more the inconsistency of these two tests, which are supposed to prove the same thing.

The glasses were then reversed; and four days later the patient reported that he could read very well with the prisms placed bases in, but that all his nervous symptoms, such as fatigue and distress in the head, had returned with their accustomed sequelæ.

The prisms were again placed bases out, and gave immediate relief. He was enabled to do some literary work, and did not become so exhausted upon slight effort. He was kept under observation for nearly eight weeks, and tested frequently. The relief afforded by the prisms, which was so marked at first, gradually diminished until, in the latter part of January, the eyes ached at night very considerably, and the patient was obliged to relinquish all work on account of the general symptoms. During this period the muscle tests ran pretty uniformly, as follows: Prisms overcome, at a distance of twenty feet, two degrees base up or down, six degrees base in, twenty-two degrees base out. Vertical diplopia test required five degrees base out, to place images vertical.

On February 2d, 1889, I did a partial tenotomy of the internal rectus of the left eye. About four to five millimetres of a very broad insertion were cut. Operated under cocaine. An immediate trial with candle and red glass showed a crossed diplopia. In five minutes, however, it had disappeared. The operation was not immediately followed by any gain, except that dizzy sensations in the head, to which he had before been subject, had entirely disappeared. Twelve days after the operation the Graefe vertical diplopia test showed muscular equilibrium.

On March 2d, patient reported that he felt distinctly better. His eyes were comfortable; his neuralgias had disappeared; he had no dizzy spells or trembling attacks; and, to judge by his face and general appearance, one would say that he was evidently much better.

In response to a letter of inquiry, the gentleman writes me, under date of April 16th: "I began preaching after I saw you, and have been able to keep it up every Sunday, once a day; but I have felt rather exhausted some of the time. On the whole, there has been a gradual improvement, — I ought to say, a very decided improvement in some respects, — and I am still gaining. . . . The ability to do some professional work must be attributable largely, if not entirely, to the operation; and this is a gain of incalculable value."

I have reported these cases more at length than I should otherwise have done, but for the desire on my part to emphasize the utter unreliability of the results of any single examination for proving the existence of insufficiencies of the ocular muscles.

If the cases are studied in detail, it will be found that the condition that was ultimately proved to be the cause of all the disturbance was rarely discovered at the first examination, and that it was only when the muscles had been relieved of their extra load, by the use of prisms, that the true state of affairs was revealed. Again, what is to be especially noticed in these cases is the fact that the von Graefe test for insufficiency and the ability to overcome prisms, which are supposed to be only different methods for arriving at the same facts, should so frequently show exactly opposite results. From my experience in these five cases I should say that, while I would not discard the trial of the ability of the muscles to overcome prisms, I should rely much more upon the results of the von Graefe test. I desire also to call attention to the fact that the constant use of prisms for a few days was a much more satisfactory method of trial. It is evident from the results obtained in these cases that when the weak muscle had an additional burden laid upon it by the prisms, that the disagreeable symptoms were aggravated, and *vice versa* when the burdens of the weak muscles were relieved and the severity of the symptoms abated.

With regard to the ultimate results in the cases reported, it would seem that if the incision had been a trifle freer, so as to have weakened the muscle a trifle more, that the results might have been better in the first, second and third cases. In the fourth case the result, although so far a failure, is so, apparently, because there is still a large amount of lateral insufficiency left, and also, probably, because there is a certain amount of vertical insufficiency which has never been corrected.

The results obtained in the first, second, third and fifth cases are highly satisfactory to the patients and encouraging to the operator, and have been accomplished after all other means had been tried and failed.

A word as to the number of such cases, and then I am done. From an ophthalmologist's point of view I should say that they were not numerous. The vast majority of cases of headache and neurasthenia, which have the eye for their starting point, are completely relieved by properly correcting glasses, and this too, when an insufficiency exists, according to the von Graefe test.

The correction of errors of refraction in neurasthenic cases should be done with the utmost care. An error of half a diopter in a spherical lens, or of ten degrees in placing the axis of a cylindrical lens, is sufficient to continue nervous disturbance.

A number of times, when I thought I had gotten another case to add to the number reported here to-day, I have found that I was mistaken, and that all that was needed was a more careful examination for errors of refraction than the patient had hitherto received, and a very slight alteration in the formula.

I say that these cases are probably rare, for the reason that I have been industriously looking for them for three years among all the clinical material at my command, and I have only found three cases in addition to those reported. These three cases all refused operation. It is probable that such cases may be more numerous in neurological than ophthalmological clinics.

In conclusion, while I am not in a position to judge as to the efficacy of partial tenotomies for the treatment of epilepsy, insanity, etc., I do believe that it is of great advantage in a certain class of neurasthenics.

FRACTURE OF THE SPINE.

WITH A CASE TREATED BY THE PLASTER-OF-PARIS JACKET.—DEATH.

BY U. O. B. WINGATE, M. D., OF MILWAUKEE.
Visiting Surgeon to the Emergency Hospital.

THE advancement made of late in the surgery of the brain and spinal cord seems to call for a full report of all cases coming under observation, whether originating from traumatic or other causes.

The following case, together with the remarks appended thereto, is related simply as additional evidence

to that long list of cases which may some time furnish material for useful conclusions.

F. R. D., a healthy man, thirty-six years of age, by occupation a carpenter, was struck in the back by a swinging blow from a heavy staging. He appeared much hurt, was first taken to his home, then brought to the Emergency Hospital, where he was entered about noon, November 5th, 1888. I saw him very soon after he was admitted, which was about two hours after the receipt of injury. He was suffering from severe shock; complained of great pain in the back; mind was clear; there was a marked deformity of the spine near the junction of the dorsal and lumbar vertebræ. The upper portion of the spine appeared to project slightly out over the lower portion. There was complete loss of motion and sensation below the seat of injury; retention of urine; no priapismus; no crepitus could be made out.

At 4 P. M. the patient, having rallied somewhat from shock, with the kind assistance of a number of gentlemen of the hospital staff, was carefully etherized and suspended *à la* Sayre, extension made, and the deformity reduced. A plaster-of-Paris jacket was then with much difficulty applied. The patient became pulseless, and had to be let down twice; but he came out from the ether well, and was much relieved of his pain. Unfortunately the material for the plaster bandage was poor, and the jacket was unsatisfactory.

November 6th. There is partial return of sensation in the lower extremities, but no return of motion. There is some pain, which is relieved by small doses of morphia administered subcutaneously. Tympanities is troublesome; relieved by several punctures into the colon through the abdominal walls, made by a small aspirator needle. No harm came from these punctures, the needle being thoroughly aseptic.

November 7th. The jacket being so unsatisfactory, it is removed; the patient again suspended, this time without an anæsthetic; and a very satisfactory jacket applied. Much pain is produced; patient let down twice in nearly a collapsed condition. After a period of rest he appears quite comfortable.

November 8th. Numbness of right hand complained of, and it is found that the hand and arm are nearly powerless. Much headache.

November 12th. Severe cystitis; headache better; right hand and arm the same; sensation improved. Bladder washed out twice daily with a four per cent. solution of boracic acid.

November 15th. Much pain in the feet and legs.

November 18th. Improvement in the right hand and arm.

November 21st. General improvement. Nearly normal sensation and strength in right hand and arm.

November 28th. On account of a bed sore appearing above the seat of injury, the jacket was removed. Patient can be moved without pain. A small amount of morphia is required at night to insure sleep.

December 4th. Cystitis much better. Right hand and arm fully recovered. Bed-sore healing nicely under a dry dressing of one part tannic acid and two parts iodoform.

From this time to December 25th he seemed comparatively comfortable and holding his own; then he began to fail.

December 31st. Has been failing for several days. Cystitis not troublesome; bladder requiring to be washed out every second day; very little pus. Bed-sore nearly healed. Nearly normal sensation in lower extremities, but no return of motion; appetite, which has been good, is failing; sleep poor. The childish, peevish mental condition which has been prominent throughout is more marked; there is great mental depression, loss of hope and general failure. In a word, the back of the patient seems to be broken in more than one sense. At this time my term of service at the hospital expired, and the case went under the care of my colleague, Dr. Chandler, who reports gradual failure, and the patient died on January 10, 1889, sixty-six days after the receipt of injury. For some reason a complete autopsy was not made, but a portion of the spine was removed which showed a fracture through the body of the first lumbar vertebra, the vertebra being crushed downward and inward upon itself somewhat like a crushed hat; there was also a fracture through both laminæ, also of several transverse processes. No direct pressure was sustained by the posterior part of the cord, but the anterior portion sustained a pressure from the bony formations resulting from the crushing in of the body of the vertebra and the attempted reparative process which was thrown out in a way to diminish the lumen of the spinal canal in a marked degree.

The cord was subjected to pressure at a place just above the corda equina, at which point it showed evidences of marked degeneration. The temporary loss of power in the right hand and arm was supposed to be due to some slight pressure in the cord above the seat of injury, probably from a small clot of blood which soon became absorbed.

There are two points of some practical interest connected with this case, namely, the treatment, and cause of death, to which I desire to refer in a brief manner.

In a very able and concise paper read before the Massachusetts Medical Society, and published in the Transactions, in 1887, by Herbert L. Burrell, M.D., of Boston, under the title of "The Immediate Treatment of Fracture of the Spine by Rectification of Deformity and Fixation by Plaster-of-Paris Jacket," the author, it seems to me, closes his paper with a most valuable conclusion, namely, "My own belief regarding the status which the procedure should occupy in surgery is, that it will occasionally be a life-saving measure; that it should be applied under anæsthesia in all cases of fracture of the spine which are not conclusively known to be irremediable; and that, apart from the chance of recovery offered to the patient by this means, it will almost invariably make the patient more comfortable, in that he can be handled more easily."

Such a conclusion I would but slightly modify at the present time. In the case above reported, on account of the modern brilliant results of operations upon the spinal column by Macewen and others, the question of operating came up. That there was pressure on, or injury to the cord, or both, was evident from the symptoms. Could an operation be done to relieve the cord of pressure, if such existed? Judging from the character of the blow received, the position of the spinal column and the absence of crepitus, I was convinced that there was either a fracture or dislocation, or both, of the bodies of the vertebræ, and that no operative measures, other than that adopted would be justifiable.

On examining the specimen of the spine removed, I think any surgeon will readily understand at once the

utter impossibility of remedying the injury by an operation. There is but one part of the spinal canal that can be attacked surgically, as has been pointed out by all writers from early times to the present, and that is from the posterior part through the laminæ. To attempt it from the front or side is impossible at sight.

Macewen, whose results have excited the admiration of all surgeons, says: "Traumatic lesions are, as a rule, so gross, and the destruction so complete, that, in such, operative treatment can be of little service. Still there are cases in which traumatism has produced localized pressure, primary or secondary, which can be relieved."

In this case, although the laminæ were fractured through, there were no fragments pressing on the cord from this source; but the entire direct pressure came on the anterior part of the cord from the crushing in of the body of the vertebræ, and as time progressed the attempted process of repair also being thrown out, added to this, and gradually diminished the lumen of spinal canal. It is true that, by removing a portion of the posterior arches, the indirect pressure would have been relieved; but the direct pressure, which was doing the mischief, pressing upon the cord precisely as a bridge of a violin presses upon the strings, could not be relieved, and any operation with such an end in view would only have added injury to injury to a most unfortunate man. Certainly at the present day no case of injury to the bony spine where there is any evidence of pressure upon the posterior part of the cord should go unrelieved by operation, but where such evidence does not exist, is a surgeon justified in making an exploratory operation on patients in the condition in which we observe this class of cases? I am not yet convinced that past experience or present and future prospects justify such a course, and desire for myself, should I meet with such an injury, to be spared from such surgery.

The relief from pain, and the ease in which this patient could be moved by his attendants after the plaster-of-Paris jacket was applied, were very evident and satisfactory.

In regard to the second point, namely, the cause of death in this case, it has occurred to me that the severe effects in the nerve centres, in this class of injuries, are often underrated.

This man did not die from septic causes and exhaustion produced by bed-sores and cystitis, as many cases with such injuries appear to do, for in both these respects he was nearly well.

Of what did he die?

In that admirable paper on "Shock," read before the last meeting of the American Surgical Association by Prof. D. W. Cheever, of Boston, he states that as a first degree of shock we have apprehension, and, going on through the degrees, at last we have collapse.

In the case above reported there was severe primary shock, and the degree of apprehension was marked and prominent from first to last. The injury to the cord was sufficient to account for this. The crushed condition of the cord acting on the nerve centre reacted on the ganglia, the heart, the brain; the life kept the patient in a feverish apprehensive state of mind, and this condition of mind reacted in turn to depress the nerve centre and the life. Cheer and assurances from his surgeon and attendants would rally him somewhat from this state, but he would soon relapse again. This went on until the effects of the increased pressure on the cord, together with the progressive ascending degeneration, at last turned the tide against our efforts, and death came with collapse after the patient had passed through all the degrees of primary and secondary shock of long duration.

I would offer by way of conclusion:

(1) The plaster-of-Paris jacket, as advocated by Dr. Burrell, affords at the present time the most promising and satisfactory treatment of all fractures of the spine where the bodies of the vertebræ are involved; but in the light of recent research, in all cases where there is evidence of pressure upon the posterior part of the cord, operation to remove the posterior arches is justifiable, and only in such cases.

(2) The existence of prolonged and dangerous shock, which is so often present in this class of injuries, renders operative measures, which must of necessity be of a very severe nature, highly objectionable, unless some positive evidence is present that such an operation may accomplish positive results by way of relieving pressure upon the cord.

IODOFORM IN DIPHTHERIA.

BY WALTER LINDLEY, M.D., LOS ANGELES, CAL.

AT the recent session of the California State Medical Society, Dr. Walter Lindley, of Los Angeles, read a paper on Diphtheria, in which, after accepting the theory that the microbe is the propagator of the diphtheritic poison, he continues, "How does this poison act?"

Frequently there are deaths from diphtheria where the disease has lasted but a few days. There is no exhaustion to cause heart-failure, and no strangulation; the patient, without a pang or a single struggle, sinks into a gentle lethargy and thus passes peacefully away. In such cases there is usually scanty urine, containing from twenty to fifty per cent. of albumen. Yet there are rarely uræmic convulsions. There is no other disease in which this combination occurs: — scanty urine, retained urea, abundance of albumen, and no convulsions.

It is well known that morphine and chloroform, by soothing the nervous centres, control uræmic convulsions. Is it not possible that this diphtheritic ptomaine acts in a similar manner, quieting the nervous system, and preventing convulsions? As in the case of morphine, if there is an excess of the ptomaine, death ensues. . . .

There is one other point of great value in prognosis, and that is the amount of albumen in the urine. No physician should attend a case of diphtheria without making at least a daily examination of the patient's urine. Dr. G. W. Lasher, who has performed tracheotomy and intubation oftener than any other practitioner in our section, and who has made diphtheria a special study, recently announced in the Los Angeles County Medical Society, that he had never known a case of diphtheria to recover where there existed at any time over thirty per cent. of albumen.

Treatment. — My opinion is that the treatment of diphtheria should be based exactly on the same principles as the treatment of puerperal fever. Antidote the specific poison; the cardinal point in doing

this is to destroy, remove and neutralize as much of the poison at point of infection as possible.

When the obstetrician believes septic poisoning is taking place through the uterus, he immediately tries to destroy and remove all septic material at the point of entrance. Not harshly and with force, but with a gentle, soothing intra-uterine douche of hot water, carrying in solution a germicide.

So should the action of the physician be when he is called to a case of diphtheria. If the membrane can be removed without tearing or hæmorrhage, remove it. If it cannot be removed without force, then the utmost efforts should be used to neutralize the septic germs that infest that susceptible locality. It is true that the throat cannot be so satisfactorily disinfected as the uterus and vagina, because it is constantly open to the entrance of air, and nutrient liquids that encourage the development of bacteria are frequently passing over its surface.

Some person says, "If you cannot remove all, why remove any?" Suppose a man has taken a poisonous dose of strychnia, and you know some of it has been absorbed, would you say there was no use of removing the portion of the drug that yet remained in the stomach? We hope to destroy so much of this septic material that not enough will enter the system to cause death. . . .

My own peculiar line of treatment is the use of iodoform, locally and constitutionally. I began employing this remedy several months ago. A case of mine has just proved fatal after intubation and tracheotomy had both been performed. The case then in hand was growing rapidly worse, and the temperature had risen to nearly 105°. The liberal insufflation of iodoform every three hours was then begun, and in twenty-four hours the temperature had fallen to 101½°. The membrane in twelve hours began to have a lifeless appearance, and in 36 hours dropped off entirely. Since that time I have had eight other cases, varying from severe to mild; two being slightly laryngeal in character, four showing from ten to fifty (one case) per cent. of albumen, and all but one recovering. In all these, iodoform has been my chief reliance.

The fatal case was a delicate girl, twelve years of age, suffering from chronic bronchitis. The first day I saw her the temperature was 104°, and the membrane covered the fauces. The urine, immediately on testing with heat and acid, appeared almost solid with albumen, and after settling for twenty-four hours, was half albumen. The nasal complication was also severe. Iodoform was insufflated through mouth and nostrils at least every four hours, after spraying the parts with listerine. The instructions to the nurse were to see that all perceptible membrane was covered with the powder.

After the third day the patient began to improve, and on the seventh day there was no albumen to be found in the urine. The patient was very bright, and I felt happy at the thought that I had a case with which to negative the dictum of Dr. Lasher, that none recovered where there was over thirty per cent. of albumen.

On the thirteenth day, when we thought our patient was about well, she had a severe chill, followed by high temperature and pain in the cardiac region. On examination, consolidation of the base of the left lung was found. The breathing from this time on was very rapid, the temperature high, and the pulse weak and rapid; but neither the membrane nor the albumen returned. On the seventeenth day the patient died from exhaustion. In this case the intercurrent pneumonia evidently caused death. My experience with iodoform justifies its having a further trial. Since beginning its use I have found in current literature six brief references to the subject. In conclusion, I recommend the use of iodoform because:

(1) It prevents the multiplication of bacteria.

(2) It is a soothing local anodyne.

(3) It is like alcohol, in having no toxic dose where the patient is suffering from the diphtheritic poison.

(4) It is so near impalpable that it reaches all portions of the diseased surface.

(5) It adheres for a long time to the surface where it is applied, and thus has excellent local effect before it is absorbed.

(6) It does not cause nausea, and thus interfere with nutrition.

(7) It does not produce diarrhœa or salivation, as is possible from an overdose of the bichloride.

(8) It is quickly and easily applied.

REPORT ON RECENT PROGRESS IN SURGERY.[1]

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

EXTIRPATION OF THE RECTUM.

W. Levy, Berlin, proposes the following method for resection of the rectum, which he claims to have evolved from experiments and dissection.[13] An incision is made over the sacrum eight to ten centimetres in length, and about two fingers' breadth, above the cornua of the coccyx, through the superjacent soft parts to the bone. From the ends of this incision, two others about eight centimetres long, and at right angles to it, are made through the skin and glutæus maximus muscle. A broad blunt hook is now placed in one of the latter incisions, and it is retracted strongly outward. The greater and lesser sacro-sciatic ligaments are divided to the edge of the bone in the direction of the first incision. This is now repeated on the opposite side, and the fascia separated from the anterior surface of the sacrum with an elevator. The sacrum is now cut across with bone forceps. The flap is thus formed of bone soft parts, and the skin is drawn downward, exposing the rectum, which can be removed, if desired, from near the sigmoid flexure to within two centimetres of the anus. If necessary, on account of the large size of the tumor, the left wing of the sacrum can also be removed as in the Kraske operation. The resected ends of the rectum are united by a double row of sutures carefully set. The reflected sacral flap is replaced and sutured in position, after which the skin wound in its first portion is united. The side incisions are either packed with iodoform gauze, or united, and drained through the lower ends, through tubes which reach to the vicinity of the rectum. An antiseptic dressing or continued irrigation is the subsequent treatment.

THE TREATMENT OF TRAUMATIC SEPARATION OF THE SUPERIOR EPIPHYSIS OF THE HUMERUS.

Helferich[14] treated successfully a boy who had sus-

[1] Concluded from page 230 of the Journal.

[13] Centrbl. f. Chir. 1889, Bd. xvi, p. 218.

[14] München Med. Wochn. 1887, No. 40.

tained this injury, by opening the joint after an attempt to reduce the deformity had proved unsuccessful, restoring the fragments to their proper position, and fastening them in place with an awl-like steel pin. At the end of eight days the dressing was changed and the pin removed. The joint rapidly regained its function. Lange's case[15] is the only other case on record where this has been done immediately following an injury.

CLINICAL AND EXPERIMENTAL CONTRIBUTIONS TO LIGATURE OF THE FEMORAL VEINS BELOW POUPART'S LIGAMENT.

A recent investigator of these cases[16] has collected twenty-eight cases of this operation, fourteen of which recovered. Gangrene occurred in ten of the fatal cases. From experiments von Koretzky concludes that ligature of the femoral, between Poupart's ligament and the fossa ovalis, is a dangerous proceeding; for, aside from septic dangers, which with proper care may be overcome, Braune has demonstrated the existence of valves in all the veins given off at the fossa ovalis. These valves open towards the common femoral, an arrangement which makes the common femoral the only vessel relieving the return circulation of the lower extremity. The common femoral has no collateral branches. In an anomalous absence or insufficiency of the valves of the internal circumflex vein, this vessel could act as a collateral branch. A pressure of even three metres of water was found insufficient to overcome the resistence of these valves. Advanced age, chronic inflammation or tumors, may produce a collateral circuit from the thigh backward through the veins of the pelvis. Aside from this, Koretzky asserts that a third circulus venosus exists; namely, the circulus venosus subtubere ischii. In advanced age ligation of the femoral is less dangerous.

EXCISION OF BONE TO PROMOTE HEALING OF THE OVERLYING SOFT PARTS.

At the Medical Society of London,[17] Mr. Annandale contributed a series of cases treated by the above method. He says that he and other surgeons meet with cases of large sores which cannot heal because their thin edges are held agape by the bone beneath. Instead of resorting to amputation for these cases, he urged that a sufficient length of the bone or bones of the limb should be excised to permit of the approximation of the edges of the sore and its speedy cicatrisation. Other cases occur, particularly after burns, where an extensive, deep, and tight scar flexes a joint, effectually prevents extension, and in that way seriously cripples the patient. These cases have heretofore been left alone, or ineffectual attempts have been made to splice or stretch the scar. The author of the paper has dealt with them in quite a different way. If the soft parts are too short to permit of the use of the bones beneath, and cannot be lengthened, he shortens the bones. He has, therefore, excised considerable lengths of the bones of the elbow, and has obtained good results — useful, movable joints. Again he has applied the same principle in a case of fracture of the tibia with comminution, where, when the loose fragments of the bone had been removed, a gap remained, which failed to fill up with osseous tissues. A corresponding length of the fibula was removed, which allowed the two ends of the tibia to be approximated and to unite. All these cases are extremely interesting, and form a valuable addition to our knowledge. The treatment is, in reality, an example of "conservative surgery." Hitherto, in such circumstances, the choice has laid between a useless limb and amputation. And the sacrificing of a small portion of a member to restore the function of the whole is but a new application of the old principle of "conservative surgery."

THE TREATMENT OF CAVERNOUS ANGIOMA.

A spontaneous cure, where such tumors exist on the body, results, according to the conclusions of Mosetiz-Moorhof,[18] from (1) the obliteration of the afferent and efferent vessels; (2) spontaneous coagulation of the blood in the interspaces of the growth; (3) progressive limitation and final obliteration of these interstices, in consequence of a chronic inflammatory thickening of the framework of the tumor; (4) compressions from increase of surrounding fat tissue; (5) destruction of new growth by ulceration. These processes pass in review before the surgeon seeking a means to exterminate a growth of this nature. The two methods at present in vogue aim at the destruction or removal of the tumor. The simplest method aims to produce an artificial coagulation which should result in an obliteration of the growth. For this purpose Mosetig-Moorhof has recently used peroxyde of hydrogen. A child, eight days old, who had an extensive cavernous tumor of the right thigh, was relieved after nine injections (each 5.0 c.c.) into the midst of the growth, combined with central compression.

A MODIFICATION OF THE MACEWEN OPERATION FOR GENU VALGUM.

Dr. E. Hahn-Friedrichshain[19] claims that the usual operation is much more quickly and easily performed, in patients having large, firm bones, by operation through a double lateral incision, so that the femur can be chiselled from the outside as well as the inside. He has performed the operation in this manner in seven cases, to be subsequently reported in detail.

WLADIMIROFF-MIKULICZ RESECTION OF THE FOOT.

Bauerhahn[20] has reviewed the literature of the subject to date, and reports the results of twenty-seven cases. The resection has been done in a majority of cases for caries; in one case, on account of the defect resulting from a syphilitic ulcer. The results of trauma and sarcoma were the indications in the other cases. A radical cure from tuberculosis is not assured by this procedure, recurrence having occurred in four cases of Fischer's, in five of Lesa's, and in one of Rose's. According to *Lesa's* experience, it is especially liable to recur in young patients (three cases under twelve). Bauerhahn asserts that, after the operation, no apparatus is required. The resulting stump is suitable for standing or walking, and especially satisfactory in traumatic cases. The walking surface is greater than after a Syme or Pirogoff operation, and the toes, after a time, become quite elastic. The results are equal to those of other osteo-plastic operations on the foot.

LINEN SUTURES.

Heyder Bonn[21] claims that linen thread is as valu-

able for sutures or ligatures as silk or catgut. It is prepared by soaking for twelve hours previous to an operation in a one per cent. solution of sublimate, and during the operation the usual one-tenth per cent. solution. Trendelenburg's experience shows that wounds heal as readily and without suppuration as when silk is used. Heyder Bonn reports a case where it was satisfactorily used for an intestinal suture.

PEAT MOSS AS A SURGICAL DRESSING.

The investigations of N. N. Jakimovitch [22] of this tensively recommended substance are important to those who are in the habit of using the sphagnum for surgical dressings. He found that peat moss is far from being an aseptic or antiseptic dressing, and contains mould fungi of various species of pencilium glaucum, and at least three different species of large and small micrococci. It is friable, becomes easily pulverized, and dusts out of the pails in which it is often used, soiling the patient's linen and contaminating his wound. It does possess a high absorptive power; but, to be fit for surgical use, it requires a most careful preparation to make it fully aseptic.

Clinical Department.

A CASE OF CEREBRAL SYPHILIS FOLLOWING AN ATTACK OF THERMIC FEVER.

BY LEWIS H. ADLER, JR., M.D.

Resident Physician, Episcopal Hospital; late Resident Physician, University Hospital, Philadelphia, Pa.

IT is a well-recognized fact that any cause which is able to induce an inflammation of a nerve centre, may, when present in a syphilitic person, provoke an outbreak of specific disease. Such an instance is recorded in the *Journ. de Méd. et Chir.* (Paris, 1879, p. 191), in which the attack followed a sunstroke.

Prof. H. C. Wood has seen in an extensive practice but one similar case, besides that of the patient whose history I record, and who was under Dr. Wood's care at the University Hospital.

E. L. C., age thirty-six, a widow, white, was admitted into the University Hospital, October 3, 1888, suffering from supposed uterine trouble. Her mother, who was harmlessly insane, due to softening of the brain, died at the age of fifty-two. Father, aged fifty-eight, is dead, also; cause unknown. Two children died of phthisis, aged respectively twenty and twenty-one. Rest of family history unimportant.

Personal History.— Patient never was strong and was of a very neurotic temperament. Menstruated at sixteen. Always regular up to a few years ago. Was married at age of twenty-two. Husband was healthy, but contracted dysentery in the army, from which he died. Had three children by him and two miscarriages. Causes and time of abortions not known. Memory very defective and history, therefore, somewhat uncertain and confused. Children are still living and apparently healthy (?) Labors were all natural but very severe. Each time was confined to bed for periods varying from one to two months.

About a year before present trouble caused her to seek relief in the hospital, she had a severe attack of thermic fever, which was followed by intense and persistent headache, difficulty in speech, failure in memory, general drowsiness, attacks of giddiness and paralytic seizures of more or less moment, and of varying duration. The above facts in reference to the sunstroke and its accompanying sequelæ were not known for some time after patient was admitted into the house, and then only by accident, after she had an attack of palsy which led to further and more extended inquiries that elicited the statement from her friends as already mentioned.

Her *present illness* for which she sought relief, began two years ago. Menstrual periods became very irregular, absent sometimes for four or five months. Would then occur suddenly and last for three or four weeks, during which time considerable fluid would be lost and she would be left very weak. The last time "period" came on, it lasted two months, and clots of blood were passed causing bearing down sensations, but no pain, to speak of. This attack left her very weak, and from her own statement, as well as her friends, she had lost much flesh.

Prof. William Goodell at this time had the patient in his wards, and an examination made by him revealed

a somewhat tender and prolapsed ovary upon the left side; a small bi-lateral tear of the cervix uteri, and the womb bound down to some extent by adhesions. Her general condition did not warrant operative interference, even had that step been deemed advisable. She was therefore, placed upon medicines of a tonic nature and kept at rest in bed. This treatment was kept up for some little time, and though it improved her condition somewhat, her progress toward health was not marked. About a month after her admittance into the hospital I noticed, in making my morning rounds, that patient was very stupid and drowsy, and unable to answer questions readily. This condition grew worse, and at night she was in a profound stupor from which it was impossible to arouse her. It was noticed at this time that the right pupil was markedly dilated and the left one about normal. At first it refused to contract to light, but about an hour later responded to light from a candle (though very sluggishly).

The next day she was quite rational and able to talk. It was at this time that specific trouble was suspected, and a careful examination to confirm this view was now made, resulting in finding marked tenderness along the crests of the tibiæ, and the soft palate was found to be entirely ulcerated away. There was also evidence of pre-existing buboes. Tenderness was noted along the nerve trunks, especially of the arms; absent, however, along the spinal column.

The case was now turned over to Dr. Wood, and at his suggestion was placed upon the mixed specific treatment, consisting of potass. iodide, grs. xx, and hydrarg. bichlor. corros., gr. $\frac{1}{24}$ t. d.

It was now observed that the pupils were unequally dilated; that the tongue was drawn to the right side and that the corner of the mouth on that side was lower than the left. There was also distinct though not entire loss of sensation in both arms. Power was greatly diminished. Sensation was retarded on both sides of chest and abdomen. There was no loss of motor power or of sensation in the lower extremities. Ptosis was present on the right side. The potass. iodide was now increased to grs. xl, and the bichloride to a twelfth, t. d.

Examination of the urine resulted negatively. Patient still continued to improve. Headache grew better and the change was generally marked.

Ten days after the last increase was made in the potass. iodide, it was again increased to one dram t. d. This dose, together with the $\frac{1}{12}$ gr. bichlor., was kept up for some time until diarrhœa ensued, when they were both reduced.

After a month and a half of this treatment, patient was hardly recognizable as her former self. Had regained flesh and was mentally, as well as physically improved. The paralysis had long since disappeared, and she was able to be up and about. She was discharged and advised to pursue treatment for some time to come.

At last accounts she was doing well and had no return of previous attacks. Her head was also comparitively free from pain.

At the onset of the attack of coma, which occurred in the hospital, the patient was perfectly quiet and relaxed. There was no evidence of hemiplegia or of palsy, although after recovery of consciousness paralysis was noted.[1] That the diagnosis of cerebral syphilis was correct in this case, I think the evidence upon the patient's body conclusively proved, and was further decided by the so-called therapeutic test, about which Prof. H. C. Wood speaks in the following terms: — "In all cases of doubtful diagnosis the so-called therapeutic test should be employed, and if sixty grains of iodide of potassium per day fail to produce iodism, for all practical purposes the person may be considered to be a syphilitic. No less an authority than Seguin has denied the validity of this, but I believe, myself, that some of his reported cases were suffering from unsuspected syphilis. I do not deny that there are rare individuals who, although untainted, can resist the action of iodide; but in ten years' practice in large hospitals, embracing probably some thousand of cases, I have not met with more than one or two instances which I believe to be of such character; of course in making these statements I leave out of sight persons who have by long custom become accustomed to the use of the iodide, for although in most cases such use begets increase of susceptibility, the contrary sometimes occurs. Of course the physician who should publicly assert that a patient who did not respond to the iodide, had syphilis, would be a great fool; but in my opinion the physician who did not act upon such a basis would be even more culpable."[2]

The symptoms which occurred soon after the attack of thermic fever, and which plainly pointed to a specific origin, evidently were prematurely induced by the sunstroke. The case is interesting on this account, as well as from its curious manifestation of disease which led to a correct interpretation of the true trouble and finally to, if not its cure, its amelioration.

[1] Similar cases are recorded by Dr. J. Althaus. Medical News, vol. xlix, p. 428.

EARLY DIAGNOSIS AND OPERATION IN A CASE OF ULCERATIVE APPENDICITIS.

BY BURNSIDE FOSTER, M.D., MINNEAPOLIS, MINN.

A BRIEF report of the following case, which recently came under my observation, will, I think, be of interest to the readers of the JOURNAL.

I was asked by my friend, Dr. Knut Hoegh, to see in consultation H. M., a Norwegian merchant, age 37. For the last six or seven years he had been subject to attacks of colic, at first of moderate intensity, but which, later, became more frequent and severe. These attacks were usually accompanied by diarrhœa, but the patient could not say whether this preceded or followed the attack. At first there would be intervals of six months or so between the attacks; but during the last fifteen months there have been five attacks, each one worse than the preceding; and he would be left weak and ill and unable to attend to his business for many weeks at a time. Sometimes the attacks would come on at night while he was asleep, and he would be waked up with an aching pain over the whole abdomen, which would always settle in the right iliac region. The pain would steadily increase, and would often be accompanied by chills and attacks of shaking. There was nausea and wretching, but never vomiting. There was always extreme pain and tenderness in the ilio-cæcal region over a space the size of a silver dollar. There was sometimes difficulty in urination, but he never passed anything abnormal, and there have been no signs in the urine.

[2] Wood. Pepper's System of Medicine. Vol. v, p. 1013.

No blood or anything abnormal has been passed by rectum. Lungs and heart apparently healthy. He complains of a constant feeling of being bloated, — as if his bowels had not moved sufficiently. Appetite usually good, and he is never distressed by food.

The above history was obtained from him in June, and he was treated symptomatically, and sent back to Dakota, where he remained without any improvement until early in August.

I first saw the patient August 15th. A careful physical examination, both externally and by the rectum, failed to discover the slightest tumor or swelling in any part of the abdomen; but midway between the umbilicus and the spine of the ilium, over the ilio-cæcal region, there was a spot about the size of a silver dollar which was very tender on pressure. Dr. Hoegh and I arrived independently at the same conclusion, that there was some inflammatory trouble with the appendix vermiformis, and that the patient's condition justified an exploratory operation. The patient himself, an intelligent man, agreed to anything which offered a hope of relief.

August 19th, the patient having been kept for a couple of days on liquid diet, under chloroform anæsthesia, Dr. Hoegh made an incision about four inches long in the right linea semilunaris. On opening the peritoneum, the cæcum and appendix were readily found, the latter pointing downwards and toward the median line. The process had a peculiar, firm, elastic feeling, and was about two inches long. At its base there were some not very fresh adhesions, which were easily separated, The process was ligated at its junction with the cæcum with stout silk, and amputated. The serous surfaces were stitched over the stump with fine silk. Dry gauze napkins, previously boiled, were used instead of sponges, and the wound was kept perfectly aseptic. The edges of the wound were united throughout and closed without drainage.

At the conclusion of the operation the appendix was examined, and presented the following condition: It was about two inches long and somewhat thickened in the centre; the opening into the cæcum was quite contracted, being smaller than the lumen of the process; on opening it, there escaped at once about half a drachm of dark brown pus, the odor of which was fetid rather than feculant; the mucous membrane was the seat of two ulcers, neither of them very deep; the largest one was near the centre, being about a quarter of an inch in length, and occupying nearly the circumference of the appendix; the other smaller one was near the apex, and was about the size of a split pea. The subsequent history of the case has been uneventful.

Dr. T. H. MANLEY read a paper on

THE OPERATION FOR STRANGULATED HERNIA BY THE MCBURNEY METHOD, WITH REPORT OF THREE CASES.

Since January 1st of the present year, he said he had had in his hospital service three cases of strangulated inguinal hernia, all of which were operated on as quickly as possible after admission, with a view not only to relieving the constriction, but also at the same time permanently curing the patient by means comparatively simple, and by all odds the safest yet devised. For the procedure adopted in these cases the profession was indebted to one of New York's most distinguished surgeons, Dr. Charles McBurney, who had thus added one more gem to the diadem of American surgery.

McBurney's operation was characterized by a few cardinal points which were decidedly original, and which, if well understood and skilfully applied, must always lead to successful results. These were: (1) An open wound; hence no septic infection or purulent infiltration. (2) The excision of the sac. (3) The suturing of the cutaneous and aponeurotic edges of the wound together. (4) The closing in of the breach by connective, scar or cicatricial tissue formation.

The difference in the character of the three cases in question rendered necessary some modifications in their management; but in all, there were followed out the fundamental points laid down by McBurney, whose operation was recommended for every variety of abdominal protrusion, wherever or whenever found.

The first case was that of a male forty-five years of age, whose hernia, on the left side, had existed as long as he could remember. From time to time the protrusion would disappear spontaneously, though he always wore a truss; and up to the day before he entered the hospital the patient had not noticed it for more than four months. On this day, after unusual straining at stool, the tumor reappeared larger than ever, and unusually tender to the touch. The man himself and his family physician both having failed in reducing it, he was sent to the hospital, where he was seen by Dr. Manley. At this time there were no signs of strangulation, and as his condition was very good, he refused to submit to an operation, which was strongly urged. Topical applications were applied for the purpose of favoring reduction, and these were followed by temporary relief; but, four days after the reappearance of the hernia, well-marked symptoms of strangulation declared themselves.

The patient was now eager for the operation, and an anæsthetic having been given, the skin was quickly opened by one bold stroke of the scalpel carried from a point just over the internal opening of the inguinal canal to an inch below the external ring, and then the coverings were divided until the sac was reached; the upper part or neck being first sought, and the body cut down later, The sac was found to be an old one, and bound down by very firm adhesions, which were separated only with the greatest difficulty. Within the sac was found a knuckle of intestine, with a large quantity of effused serum. It was calculated to leave the spermatic cord alone in operating; but in this case there was no spermatic cord, either within or without the sac. When the canal was opened the cause of all the trouble was found, viz., an undescended testis, which was normal in shape, but was not larger than a kidney bean. By making considerable traction it could be readily brought out of the canal, and Dr. Manley considered the fact that the inguinal opening was patent throughout its entire length, attributable to the defective development, the testis sometimes slipping down through the ring when there was much straining, and then

returning again. This condition had naturally kept the patient in a constant state of danger, and the displaced testis was also the cause of the constant discomfort which he said he had experienced when wearing a truss. After opening the canal throughout and removing the testis, traction was made, and the whole of the protruding portion of the serous sac ligated and cut off. The cutaneous edges were drawn down to the divided edges of the canal, and six sutures put in on each side; after which the open wound was packed with iodoform gauze, and the usual antiseptic dressings applied. After the operation the patient never rallied, and death ensued four hours after its completion. This man's life, Dr. Manley said, should have been saved, but it was lost through his refusal to submit to an early operation, — the delay resulting in septic infection of the peritoneum and general exhaustion of the system.

The second case was in a male twenty-nine years of age, who had worn a truss for many years, but discarded it about a year before, when his rupture disappeared. It suddenly returned one day when he was making severe exertion, and several physicians having failed to reduce it, he came to the hospital. As in the preceding case, an immediate operation was advised, but the patient refused, and the tumor, which was very small, remained unreduced in spite of all that could be done. The next day there was a marked change for the worse, and locally there was found marked fullness along the cord in the inguinal canal, while the scrotum was distended with an enormous hydrocele, and the hernia itself had increased to more than five times its original size. In addition, there was well-marked peritonitis in the region of the sac, with a tendency to rapidly become general, and, altogether, septic infection was evidently in full progress.

Under such circumstances, the success of any cutting procedure was very doubtful; but an operation was now, of course, the only resort. The great advantage of the McBurney method in cases of this kind was, that we had a large open wound for free drainage, and an opportunity to remove, as occasion required, any diseased or contaminated tissue met with. In this case the hernia had no sac. As in the preceding instance, there was an old congenital impediment (though the testis had descended), and the spermatic cord dangled in the centre of a large pouch. Hence, to carry out the operation according to the method adopted, it was necessary either to sacrifice the testicle or make an artificial investment for it. As the latter would render the patient liable to another hernia at an early date, and, moreover, as it was found that the *vas deferens* was reduced to a mere thread in thickness, and the testis was very imperfectly developed, with no well-defined epididymis, and therefore probably useless functionally, the organ was removed. In order to secure a continuous sac, the unclosed *tunica vaginalis* had to be dissected off all the way up to its origin at the internal ring. The protrusion consisted of a small knuckle of intestine with a large mass of discolored and partly gangrenous omentum. The latter was drawn forward until healthy tissue was reached, when it was ligated and cut off. With its stump properly invaginated within the peritoneal cavity, and the omentum well up, the sac was cut off, and the wound treated in the usual way. Though Dr. McBurney laid stress upon the importance of keeping the patient six weeks in bed after the operation, this man could not be persuaded to keep quiet so long, and left the hospital perfectly well on the twenty-ninth day. (This patient was presented to the Association, and an opportunity given the members of examining the cicatrix.)

The third case was that of a woman fifty-one years of age. The hernia had existed for fifteen years; and ten days before her admission to the hospital she found it was impossible to replace it as usual. She also became obstinately constipated, and numerous enemata had no effect in relieving the bowels. On the night of the tenth day symptoms of strangulation set in, and her physician, who had previously exhausted every means to reduce the hernia, advised her to enter the hospital. She was admitted at midnight, and Dr. Manley saw her one hour afterwards, when her condition was exceedingly serious, notwithstanding the fact that from the moment of her entrance stimulants had been freely given and artificial heat assiduously applied.

The operation was commenced as promptly as possible, and on account of the extreme exhaustion of the patient, special effort was made to render it as brief as was consistent with thoroughness. When the peritoneum was reached, it was found that it had formed a pouch which was firmly adherent to the surrounding parts, and, from the thickness and toughness of its walls, undoubtedly an old one. The sac, close to the inner side of which lay the round ligament, was divided in a longitudinal direction; when it was found that the greater part of its contents consisted of omentum, which towards the neck was very firmly adherent to its serous covering. Immediately under the protruding fat was discovered a small knuckle of intestine, of a port-wine color, with its peritoneal investment, which had a peculiar granular feel. After the sac had been torn free from all its connections with adjacent parts, it was opened in the lower portion, which permitted the drawing down of the omentum to a slight extent. This having been done, it was ligated in mass, and the stump returned to the peritoneal cavity. In this case, as in the others, the inguinal canal was opened throughout its whole length.

The last steps of the operation, the sewing together of the skin and aponeurotic structures, and the packing of the wound, presented unusual difficulties in this instance, on account of the extreme amount of adipose tissue in the abdominal walls; but by somewhat modifying the *technique* of the operation, these were overcome. Though the patient was extremely weak for a few days, all her dangerous symptoms disappeared with the operation, and she made a rapid and satisfactory recovery.

Before the time that McBurney promulgated the principles for an operation which offered advantages which none yet devised possessed, Dr. Manley went on to say, the operation for strangulated hernia was attended with a fearful mortality, Bryant putting it at fifty per cent. in the hands of the best operators. By a strange coincidence, there were admitted into the female surgical ward of Harlem Hospital, during the first week in July, 1888, three women with strangulated hernia, the only women entering with this accident since the hospital had been opened. The first was a healthy, muscular individual of twenty-nine years; and the second was fifty, and though of spare figure, also sound in health up to this time; while the third was sixty-five years old, and greatly emaciated

and reduced in strength. The most persistent efforts at reduction by taxis failed; and all were operated on within twenty-four hours after the latter was abandoned. The operation was simple, as the only aim was to release the constriction at the neck and return the protrusion; but two of the patients died within forty-eight hours after the operation, and the one who recovered, strange to say, was the feeble old woman of sixty-five.

Dr. Manley said that though there might be a diversity of opinion as to the propriety of doing any operation in the case of an individual with a hernia that could be comfortably borne with the aid of an easy truss, or in the case of very young children, he could hardly conceive of any objection against a procedure which, while it obviated the greatest dangers in strangulated hernias, afforded, in addition, the reasonable prospect of a permanent cure and the liberation of the patient from the unceasing burden of a truss. There were two great sources of danger encountered in every case of strangulated hernia operated upon, which the McBurney method always eliminated. These are, first. peritonitis, from septic infection, and second, hæmorrhage. As far as immediate danger to life was concerned, all other dangers, bleeding included, sank into insignificance when compared with the first.

If there was localized contamination a free opening could be made, and the cavity of the peritoneum boldly entered. If any of the extruded part was undergoing putrefactive changes, it was removed, no matter whether it was fat or gut, omentum or mesentery. If there was reason to suspect that the serum of the peritoneum had become infected, an opening might be made by the exposure of the ring, or perhaps the crural arch; while if this were not free enough, it could be readily enlarged by an incision into the fibrous tissues, and the whole region thoroughly flushed with some efficient antiseptic wash. To be the more certain that no pent-up decomposing material remained, a drainage-tube could be introduced. If it were objected that the free use of the scalpel in dividing the strong bands of aponeurotic structure would tend to weaken the power of the abdominal walls, it might be answered that we would resort to this only in a very severe case, when general contamination was feared. Besides, immediately after the parts are well washed out, the line of incision would be solidly sutured.

As to hæmorrhage, this method marked a new era in dealing with inguinal bleeding. This procedure ended the blind groping with a stub or blunt-pointed blade for a part which should be recognized by the touch only. Under the old plan the one great thing which the surgeon found in dividing the constriction was hæmorrhage; and hence very great stress was laid on the importance of keeping well in mind the bearings of the blood-vessels, for, unfortunately for the patient, if a deep vessel happened to be divided, it would scarcely be known until after he was dead. In addition, there was such an exaggerated fear of disturbing the peritoneum that it would be only a very bold surgeon who would cut down for the divided ends of the wounded vessel. But with a free, open wound, with its edges well separated by retractors, and every part thoroughly exposed to view, the chances of hæmorrhage were reduced to the minimum, and if perchance a vessel pursuing an anomalous course should come in the way of the scalpel it occasioned no alarm whatever, since the point of injury would be in full view, and the bleeding could be readily controlled by the clamp forceps. The importance of avoiding hæmorrhage was still more appreciated when it was remembered that hæmorrhage, independent of the quantity of blood lost, may become a source of danger by exciting inflammation, and possibly spreading infection. It was well-known that the presence of even a very small quantity of blood would often interfere with primary union of a wound, and in this operation the tissues were not permanently brought into apposition until every vestige of bleeding had ceased.

A very interesting feature of Dr. Manley's three cases was the anatomical arrangement of the structures in the inguinal region. In no one of them did he find a true recent peritoneal sac; the hernia being either of congenital origin, or having existed for a very long time. In the first case the displacement of the structures met with was quite unique. Here it was well shown what mischief an undescended testis may occasion, and there was also observed a condition that must be rather rare — an open external inguinal ring, with the undeveloped testis lying in the position of a bubonocele, at one time sliding down and out, and again returning to its original position. In the second case, too, the opening and direct connections of the *tunica vaginalis*, the peritoneal cavity was complete, and he believed that in this instance, as in the preceding, the testis was originally lodged somewhere along the inguinal canal at birth, though at a later period it completed its descent.

In the woman was found a condition which he believed was originally attributable to defect of developments at birth; but which escaped the patient's notice until the strength of the abdominal walls was put to a severe test by a sudden strain; when this portion of the physical structure, which was weakened by some congenital defect, gave way and allowed a hernia to develop. It was thought in the text-books that in the female in early life the duplication of the peritoneum covering the round ligaments, called the canal of Nuck, which is analogous to the tunica vaginalis in the male, sometimes remains open, and hence can readily become the seat of hernia. In no other way could he account for the condition met with in this woman, and he thought that the possibility of such a thing should always be borne in mind in the case of females. The very small size of the round ligaments was also quite striking, and hence he did not wonder why surgeons so often fail to find it all in performing Alexander's operation for shortening this ligament. It could easily be seen, too, he said, that an inguinal canal containing nothing but this very small and delicate cord must needs have a very small lumen. In the case in question, however, the inguinal canal seemed to have no length; probably owing to the volume of omentum and the long displacement.

The thick and tough sac was closely adherent to the areolar tissue, and it was unquestionably a very old impediment. The pouch, originally of a thin, gauze-like tissue, had in the progress of time undergone hypertrophy and considerable change in its histological elements; and this change in texture was no doubt one of nature's ways of providing against injury, the thickening and strengthening of the covering of the extended viscera, thus affording it protection from accident.

Dr. Manley went on to say that from his clinical experience and from a most careful and extended

series of investigations on the dead body, in the male and female, adult and child, he was firmly convinced that abdominal hernia in its various forms, and especially the indirect inguinal variety, is nearly always attributable to defective development at birth, or to causes acting immediately after it. Having referred partially to his observation upon infants, he said he was furthermore persuaded that the arrest of the descent of the testicle sometimes met with is responsible for the vast majority of herniæ in males. No two hernias, he believed, were exactly alike, and if in different cases of local pathological conditions were similar, there was apt to be a wide difference in the general condition of the patients.

In the treatment of strangulated hernia by the McBurney method, among the questions which arose for consideration were the following:

(1) How soon should an operation be performed after the hernial protrusion is found to resist taxis?

(2) What are the circumstances which call for a modification of the *technique* of the operation?

(3) What are the dangers, immediate and remote, in the operation, and how can they be obviated?

(4) What class of cases should be rejected?

The first question was more important than all the others, and upon its decision the success of the operation would in a large measure depend. Dr. Manley's recommendation was that whenever a case of hernia which cannot readily be reduced is met with, an immediate operation should be advised, provided the facilities to do it and for carrying out the most rigid antiseptic treatment of wounds are at command. Under such circumstances the patient is not worn out with agonizing pain and exhausting vomiting, but is in good condition and almost certain to make a rapid and permanent recovery. What could be promised now, (and this constituted one of the principal inducements for an early operation) was something which had hitherto been unknown, namely, a complete cure of the hernia. If the patient was in a vigorous condition but afraid of general anæsthetics, a few cocaine injections would suffice to blunt the pain occasioned by the cutting. If the objections were raised to immediate operation that if a longer delay is allowed and we work perseveringly we may be able to return the protrusion without any mutilation it could be answered that even if we do succeed, we cannot guarantee our patient from a return of the same trouble, which is liable at any time to imperil his life again, while if we finally fail in our efforts at reduction, the chances of recovery after the operation that will then be imperative, will be much smaller than if operative interference had been resorted to earlier. Promptness in operating was, therefore, of the greatest possible importance.

In answer to the second question he would say that the wound made through the skin, fascia and fat must be dealt with differently in fat and lean subjects, and also with reference to the kind of hernia present, and the condition of the tissues, whether healthy or not. In thin individuals little difficulty would be met with in suturing the skin to the conjoined tendon and to the fascia transversalis in oblique inguinal hernia; but in the very fat, he believed it was sometimes better to omit this part of the proceedure. In his opinion a case would do equally well if, after packing the wound with guaze, the edges were brought towards each other by broad strips of strong adhesive plaster. Of course, if in any case infection was suspected at the site of incision, the wound would have to be made somewhat larger, so as to provide for free irrigation and drainage. A hernia other than the indirect oblique would not require so free an incision. In making the incision the operator should be guided by a single purpose, namely, to make it large enough to enable him to deal with the deeper structures safely and speedily. In patients suffering from great exhaustion, he believed that the surgeon should operate with all possible haste, compatible with thoroughness, and he said he could not doubt that prolonged anæsthesia was responsible for the loss of many lives. If, on exposing the bowel there were found positive evidences of gangrene, the result of too long delay, enterectomy was called for; after which the remaining healthy portion of the guts should be returned, and the operation completed in the same manner as if this pathological change had not been encountered.

In a hernia not of congenital origin, the management of the sac was a simple matter, but when its external surface was found firmly attached by old and strong bands of connective tissues, it was necessary to carefully and completely detach them before we could be quite certain that we had reached the free floating covering of peritoneal tissue which must be shut off by the ligature applying high up, before the sac was divided. With recent protrusions, accompanied by inflammatory exudations of lymph, it was very easy to separate the adhesions, but in irreducible and incarcerated hernias, and those of the congenital variety, the most cautious and tedious dissection, in order not to injure the parts, was often required. To an operator familiar with the anatomy of the region, and with the tissues met with, such adhesions were, however, objectionable only because they prolonged the operation. In every instance when, on cutting down upon a hernia, it was found to be one dependent on defective development or misplacement of the testis, and likely to occur again in consequence of this impediment, he thought the surgeon should not hesitate to castrate. If the testicle had been an active factor in the production of the hernia, it was, in his opinion, pretty sure to be feeble in function; but, even if this were not the case, the man would still possess full virile power with the other one remaining. With this impediment removed, and the spermatic cord out of the way, we could solidly seal the whole chasm in the abdominal wall, and thus obviate the risk of leaving what might, later, possibly lead to a repetition of the same trouble.

In the inguinal region there was considerable anatomical and histological differences between males and females. In women the skin was very thin, and, if they had given birth to many children, it was usually wrinkled, atrophied and destitute of strength or elasticity. In those past middle life, too, there was apt to be a large deposit of fat, which, while it did not interfere materially with completing the toilet of the wound, did most decidedly retard the healing process. In such cases it was imperative that the union of the wound should begin at the base, and thus gradually gather in, and draw the article towards the the centre, as it proceeded outwards.

Iodoform, dry or rubbed into the meshes of cheesecloth or gauze, he went on to say, should be used sparingly with the first dressing, unless, for special reasons, septic infection were feared. This precaution should be taken with the primary dressings until the

patient's tolerance of the drug could be well ascertained, since otherwise its toxic effects upon the system might be serious. If it was found, however, not to excite undue irritation or produce other unpleasant results, its use would no doubt tend to keep the wound sweet, and shorten the healing process. In ordinary cases, where there was little tension, the catgut ligature was perhaps the most useful; but where there was any resistance, or where it was desirable to retain the parts in apposition for any considerable length of time, silk or strong linen was preferable. For ligating the sac or omentum strong silk only should be used, because it was the most reliable, and, if first rendered thoroughly antiseptic, it could be safely buried in the tissues without giving rise to irritation or ulceration.

It was seldom, indeed, that hæmorrhage would occasion any difficulty in this operation. When, however, the ordinary resources failed to control the bleeding, or when the two parts of a large divided vessel re tracted, he had found the temporary transfixion ligature invaluable. Having applied this, one could go on with the operation, leisurely seeking out and securing the bleeding points, when the temporary stitch might be removed.

The only immediate dangers in the operation, other than those which had been considered, were shock and exhaustion. Having given some attention to these subjects, he stated that he would decline to operate only on those who were bordering on the moribund state, especially those in profound shock or deeply narcotized and the very old.

In conclusion, Dr. Manley said that while there could be no doubt that the McBurney operation was generally successful, and that it was the easiest of performance, the safest from septic infection and the least liable to be followed by relapse, of all, the consummation of this admirable procedure, marking as it did a new era in herniotomy, would not have been possible without the light shed upon abdominal surgery by Marion Sims, and without the discoveries of Pasteur and Lister in bacteriology and antiseptics.

In the discussion on the paper, Dr. George S. Huntington, who had assisted Dr. McBurney in a number of his operations at the Roosevelt Hospital, said that, as to the approximation of the integument and the deeper structures, the conjoined tendon and the transversalis fascia, it was for the purpose of more readily accomplishing this that Dr. McBurney advocated the passage of lateral tension sutures; and it has proved that by the careful adjustment of these tension sutures very satisfactory results were obtained. He said he should be somewhat afraid of leaving so large a wound without any sutures, as suggested by Dr. Manley in certain cases, for the reason that, on account of its large size, there would seem to be a probability of the cicatrix resulting being rather weak.

MORE COMPLETE REGISTRATION OF BIRTHS.

Dr. J. G. TRUAX moved that a committee of three be appointed by the chair for the purpose of conferring with the New York Board of Health, with a view to securing a more perfect registration of births than is now made. In the case of the deaths, he said the registration was complete, because no dead body could be interred or removed from the city without a written permit from the health department; but it was notorious that the registration of births was at present very incomplete.

In seconding the motion, Dr. ALFRED L. CARROLL said that, to judge from the New York vital statistics, as published every week, one would naturally suppose, from the preponderance of the deaths over the births reported, that the population of the city was rapidly diminishing. The simple explanation of this was, that a very considerable proportion of the births were never reported at all, and this was due principally to the fact that nearly forty per cent. of all confinements were not attended by registered physicians or midwives. Some time ago, when he was Secretary of the New York State Board of Health, he had carefully investigated the registration of vital statistics in the principal countries of Europe, and he found that in Great Britain and Germany, where the records of births were very complete, the onus of reporting all the births was placed upon the parents, or the guardians in the event of the parents' death. Through his efforts the law had now been so amended as to make this the case also throughout the State of New York in general; but this did not apply to the large cities, like New York. At present, therefore, the vital statistics of this city are absolutely worthless.

The motion having been adopted, the president appointed on the committee Drs. Truax, Carroll, and J. R. MacGregor.

— It is stated on what seems to be good authority that food preparations for infants to the amount of $10,000,000 are annually sold in the United States. According to one of the speakers at the recent meeting of the Association for the Advancement of Science, "most of these products are unwholesome," and the Government was urged to take some action.

— A lay contemporary has learned "what killed Maybrick," and answers the question by copying from "an English medical journal" the list of the drugs which were administered to Mr. Maybrick during his illness. This list is as follows:

Morphia suppositories; ipecacuanha wine; papain and iridin solution; cascara sagrada; nitro-hydrochloric acid; tincture of nux vomica; Fowler's solution; Plummer's pill; dilute hydrocyanic acid; tincture of henbane; bromide of potassium; antipyrin; tincture of jaborandi; bismuth; sulphonal; cocaine; nitroglycerine; dilute phosphoric acid; solution of chlorine, Sanitas, glycerine and Condy's fluid, as mouth washes.

— The Farmers' Alliance of Georgia have already as reported in the daily press, boycotted the undertakers who belong to the State Association, because they had agreed upon a price of coffins. "The Death Trust," as it was called, was denounced in vigorous terms. Now the Alliance goes a step further, and legislates against doctors who belong to medical associations. The resolutions adopted by the County Alliance of Johnson County, read:

"*Whereas*, we have been informed that some of our physicians have gone into a combine, or organization equivalent to a combine, that is detrimental to our interests; therefore, be it

"*Resolved*, that we publicly denounce any such organization, and also any physician who has or may hereafter attach himself to that or any other similar organization; and we will not patronize any physician who belongs to that society when we can do better."

The granger interest is indeed working itself up into a state of mind on the subject of all combinations, not only of capital but of brains.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 12, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

FRIEDREICH'S ATAXIA.

THE rare disease of the spinal cord, first described by Friedreich as "degenerative atrophy of the posterior spinal column," has ever since been of great interest to the student of nervous diseases. Its relations to tabes in the adult, its connection (real or supposed) to the development of the nervous system, and its curious generic character, have been additional features which add to its interest above many other rare affections. The reported cases are few, and the autopsies still fewer; so that each additional case is full of value.

The most exhaustive study that has yet appeared is that made by Dr. J. P. Crozer Griffith, and presented before the College of Physicians, of Philadelphia, and just published in their transactions. He begins by quoting Friedreich's original definition of the disease, which he supplements by a new one, more in accord with our recent knowledge. "Friedreich's ataxia," he says, employing this name in preference to the many that have been suggested, "is a chronic, systemic, inflammatory degeneration of the spinal cord, developing usually in infancy or childhood, and occurring in cases in which there has probably been an arrest of development of the cord during fœtal life, this being the result of some hereditary predisposition. It is situated chiefly in the posterior columns, the lateral pyramidal tracts, the direct cerebellar tracts, and the columns of Clarke; though other parts of the white and gray matter are very commonly somewhat affected, and the sclerosis extends slightly into the medulla. The affection is characterized clinically by a disturbance of the co-ordination of the bodily movements, developing gradually, advancing from below upward, and finally involving the organs of speech. Curvature of the spine, talipes, vertigo, and nystagmus are frequent. The patellar reflex is nearly always abolished. Paralysis and sensory disturbances are not uncommon in advanced cases. Trophic, vaso-motor, and visceral affections are unusual, and any involvement of the intellect is probably accidental."

In the present essay the author has tabulated 143 reported cases, including seven presented at the meeting at which it was read, and has added two other cases in a foot-note. Over 57 other cases have been reported as occurring in the families of these patients, and other possible cases are summed up in a supplementary table. In these 143 cases there have been twelve autopsies.

Although Friedreich's ataxia is, broadly speaking, an hereditary disease, direct inheritance is infrequent; but polymorphic inheritance, from other neuropathies, — alcoholism, tuberculosis, syphilis, etc., is quite common; previous ataxia or other nervous diseases having, however, far greater influence than intemperance or constitutional affections. The symptoms, contrary to Friedreich's original assertion, commonly develop early in life, much before puberty, which seems to have little influence upon the onset. The disease has been thus far commoner in the male sex, and its onset in the predisposed is often hastened by acute diseases.

The symptoms of Friedreich's ataxia are predominantly motor. In 128 cases, for instance, there was, at some period of the disease, motor ataxia. The gait, however, is more apt to resemble that of cerebellar disease than that of tabes. Ataxic station, with Romberg's symptom of increase on closing the eyes, is also common. Later on, in many cases, the arms have also become ataxic. In some of the cases the muscle sense has been tested, and it has borne no relation to the existence of Romberg's symptoms. Static ataxia is reported in a few cases, and is regarded by the author, with Friedreich, Charcot and Ormerod, as a late symptom. Tremor, choreiform movements, and spasm, are occasionally seen. Paralysis was present in 56 cases, and absent in 53. Most of the latter were early cases, and paralysis is generally considered one of the late symptoms. In many cases locomotion becomes impossible, either from marked inco-ordination or paralysis. Contractures, talipes, and spinal curvature are also apt to develop in the later stages. The electrical irritability is seldom affected. In the majority of cases the knee-jerk is lost, but its absence is not so constant as in tabes, which may be due to the fact that the lumbar enlargement is not always involved in Friedreich's ataxia. Muscular atrophy and other trophic disturbances are rare; even vaso-motor disturbances are not often seen.

In spite of the fact that the posterior columns have been found diseased in every one of the twelve autopsies, it is curious that the sensory symptoms, which predominate in tabes dorsalis, are rare in Friedreich's ataxia. Pain of any kind was reported in only 22 cases early in the disease, and was absent in 79; while the presence of lancinating pains renders the diagnosis of Friedreich's ataxia doubtful. Later on, pain is rather more common. Cutaneous sensi-

bility is seldom much affected, and paræsthesia is distinctly rare.

In 107 cases the speech was more or less affected, generally as a later symptom. The movements of the tongue are occasionally affected; and the face and the muscles of mastication and deglutition are sometimes involved. Oculo-motor paralysis is rare, and the characteristic pupil of tabes is never seen, while nystagmus is a characteristic symptom of the late stage of the disease. On the other hand, vision is seldom affected and optic atrophy seldom or never occurs. Vertigo is occasionally present. Visceral disturbances, especially of the bladder, which are so common in tabes, are rare; and the various crises of tabes are never met with.

The present view as to the nature of the rapid process, which the author accepts, is that there is primarily an imperfect development of certain systems of fibres in the cord, due perhaps to a congenital smallness of the cord from an inherited tendency to vascular degeneration. In these imperfectly-formed fibres later on degenerative process develop in the form of a combined systemic disease. It is not yet clear whether there may be a diffuse secondary inflammation of other parts. The bulbar lesions thus far discovered afford no satisfactory cause for the bulbar symptoms observed during life, nor do we know the reason why sensory symptoms are so rare. Rütimeyer holds that the boundary layer of the posterior horn is not affected, which may be the cause, as it is constantly affected in tabes; but this requires further proof.

The disease is steadily progressive, although, as in tabes, temporary improvement may occur. The prognosis is hopeless, but the patient may live for many years, and usually dies of some intercurrent disease. Dr. Crozer Griffith's contribution is, as we have said, one of the most exhaustive that has yet appeared. It is enriched with very careful tables, and he has dealt with the material that has thus far appeared, so thoroughly that subsequent writers will have no need to do the work again.

ON THE VARIATIONS OF THE WEIGHT OF THE BODY IN TYPHOID FEVER.

Dr. L. H. Cohin has published a thesis in which he sets forth the daily variations in the weight of patients in typhoid fever. This publication is the result of studies pursued in Cochin Hospital, where, by a skilful contrivance, successive series of patients were carefully weighed every day, and the weight recorded on their charts, from the beginning to the end of the fever.

The observations of Dr. Cohin show that the loss of weight varies considerably for each individual. With some, it was 200 grammes (or between six and seven ounces) a day: this was the minimum. With others, it was 500 grammes (or rather more than a pound): this was the maximum. The mean of nine observations gives 400 grammes of loss per day; but on taking mild cases, free from complication, the mean fell to 320 grammes, which represents the daily loss in typhoid fever of average intensity. The mean of the daily gain, when convalescence was established, was 280 grammes (about nine ounces). The maximum of loss of weight corresponded to the end of the second week, or the beginning of the third. In reviewing the researches on the causes of the loss of weight in typhoid patients, the writer establishes the fact that the febricitant lives at the expense of his own substance.

The conclusions of these studies are as follows:

(1) Typhoid fever presents two distinct periods, one of loss and one of gain; certain accidental causes may modify them, but cannot affect their general character.

(2) The daily loss is due to febrile combustion chiefly, and but little to abstinence.

(3) The daily loss varies with individuals.

(4) The losses in nitrogen and in weight are almost parallel with the march of the temperature, without always following it exactly.

(5) The study of the weight-chart may aid in prognosis, a continual rise in the weight being a sign of convalescence.

(6) The complications of the disease augment the loss of weight.

(7) The study of the loss of weight enables the physician to determine with precision the action of nutritive substances in fevers.

(8) The loss of weight in a typhoid patient takes place each day in a uniform manner.

CONTRIBUTION TO THE STUDY OF THE INFLUENCE OF ALCOHOL ON PEPSIN.

Substances Antagonistic to Pepsin.

In a recent memoir, Dr. Henri de Nesslern reviews the current views respecting the influence of alcoholic preparations on pepsin, and especially the authoritative statements of Vulpian, based on the researches of his pupil Mourrut. It will be remembered that Vulpian condemned all the vinous or spirituous combinations of pepsin as inert and valueless, while Portes took a different view, affirming that it is only concentrated alcoholic solutions that have a damaging action on pepsin.

The questions considered by Nesslern are the following:

(1) Is pepsin soluble in alcohol and the aqueous solutions of alcohol?

(2) Does alcohol, even when considerably diluted, materially alter the properties of pepsin?

The results obtained are summed up in the following conclusions:

(1) The differences of opinion on the reciprocal action of alcohol and pepsin are due to the fact that the products employed were defective.

(2) A pepsin that will stand the test should not only dissolve, but peptonize albumen and fibrine.

(3) Good pepsin still preserves its digestive power in twenty per cent. alcoholic solutions.

(4) Pepsin is completely altered in its properties by seventy per cent. alcoholic solutions.

(5) As far as the wines and elixirs of pepsin are concerned, it is not by their alcohol that they render pepsin inactive, but probably by the tannin which they contain; and in the fabrication of such preparations, wines which contain little tannin should be chosen. For the *wine of pepsin* of the French Codex, Lunel wine is selected, as being most free from tannin.

According to Bardet, sugar does not impair the action of pepsin, and most of the salts are compatible with it. The presence of chloride of sodium diminishes its action, while this is enhanced by the salivary and pancreatic diastases, by liquors in process of alcoholic, acetic and lactic fermentation, by sour-crout, old cheese, etc. Lactic acid was pronounced *enpeptic* by Magendie, Claude Bernard, and Schiff, and recommended especially as a medicine by Handfield Jones. Hydrochloric acid, associated with pepsin, was a favorite remedial agent with Trousseau.

Among the substances antagonistic to pepsin should be mentioned the alkalies and alkaline bases, when in any considerable excess, as well as all metallic salts capable of precipitating it from its aqueous solution.

OPHTHALMIC MIGRAINE A MANIFESTATION OF HYSTERIA.

M. J. BABINSKI has reported several interesting cases occurring in the service of Professor Charcot, at the Salpêtrière, where attacks of ophthalmic migraine were directly dependent on hysteria, and constituted one manifestation of this neurosis.

In one of these cases attacks of hysteria were developed, and retroceded at the same time as the attacks of ophthalmic migraine. Moreover, the migraine sometimes preceded the convulsive attacks and constituted the aura; the latter was represented in other attacks by mutism. Now, as the mutism by its characters appeared manifestly to be of hysterical nature, it must have been the same with the migraine.

In another case the paroxysms of ophthalmic migraine were accompanied by hysterical manifestations, such as beatings in the temples, a sensation of constriction in the throat. It was also noted that these attacks (as is so often the case in hysteria) could be provoked by pressure over the ovarian region.

In another observation the attacks of migraine replaced genuine attacks of hysteria, and it was possible by hypnotization to reproduce and to arrest the hemicrania.

MEDICAL NOTES.

— The American Association of Obstetricians and Gynecologists will hold its annual meeting at the Burnet House, Cincinnati, O., on September 17th, 18th and 19th.

— It is proposed to endow a free bed in the Philadelphia Polyclinic Hospital, in honor of Dr. R. J. Levis, and a large committee of physicians has been formed to raise the $5,000 which is necessary for that purpose.

— The *New York Herald*, replying to a correspondent who writes to say that while scores of old men are applying for the Brown-Séquard elixir, in hope of living a few years longer, there is not a single reported case of a woman's trying the experiment, and asking if women have so hard a time that they don't care to live any longer than the allotted term, says that the real reason must be that women have more sense than men, and would rather die than be humbugged.

— There is a milkman at Brixton who has a ready wit that a lawyer might envy. One of his customers caught him watering his milk at a horse-trough the other day. "What!" said the customer, in a rage, "isn't it enough that your milk is full of typhoid without your going and watering it?" The milkman turned round, and smiling compassionately, said to two or three bystanders: "What can you do with a man like this? He actually wants his typhoid straight." — *Archives of Pediatrics.*

— The Nicaragua Canal Construction Company has just sent out to the Isthmus medical stores, cots, beds, surgical instruments, bandages, and all the equipment of a first-class hospital. The "Hondo," which sailed from New York on the 17th of August, carried with her a portable hospital capable of accommodating from eighty to one hundred persons. Dr. J. Edwards Stubbert went with the vessel. He will have superintendence of the hospital at Greytown. He was formerly connected with the Pacific Mail Steamship Company, and had charge of the Anglo-American Hospital in China at one time.

BOSTON AND NEW ENGLAND.

— Dr. Chase Wiggin, an aged physician of Providence, R. I., who neglected to report diphtheria cases to the department of health, was recently fined five dollars and costs in the District Court. It was the maximum penalty.

— The plans for the Mary Hitchcock Memorial Hospital at Hanover, N. H., have been formally accepted. Work will be commenced in season to complete the foundations this fall. The structure will be of brick, with Portland stone trimmings; about 200 feet long, with accommodations for thirty patients. The estimated cost, exclusive of land, is $50,000. The hospital corporation has organized with the following officers: President, Hon. Hiram Hitchcock, the donor; Secretary, Prof. H. A. Hitchcock; Treasurer, George Hitchcock; Trustees, Hiram Hitchcock, N. S. Huntington, George Hitchcock; Professors, J. K. Lord, A. S. Hardy, H. A. Hitchcock, E. J. Bartlett of Hanover; Professors, L. B. How, of Manchester; M. M. Field, of Newton, Mass., and Edward Cowles, of Somerville, Mass.

Miscellany.

AMERICAN SOCIAL SCIENCE ASSOCIATION.

THE American Social Science Association held its annual meeting last week, at Saratoga. The second day's meeting was devoted to the Department of Health, Dr. H. Holbrook Curtis, of New York, chairman of the department, presiding. Dr. Curtis made a brief address, and was followed by Dr. Pliny Earle, of Northampton, who read a paper on "Popular Fallacies Concerning the Insane," after which Dr. Stephen Smith, of New York, presented a report upon "The Commitment and care of the Insane," which brought out a good deal of discussion. This was followed by a paper on "The Dangerous Classes and the Modern Doctor," by Dr. Louise Fiske Bryson, of New York. In the dangerous classes the author included criminals, inebriates of all kinds, the insane, the feeble-minded, the illiterate, the poor and the uneducated. The poor, the illiterate, the uneducated, she maintained, are necessarily dangerous. When earning a living is impossible, stealing is inevitable. The pauper is compelled to use something he has not earned, and becomes at once dangerous and destructive. Restraint and labor are the great remedies for all these perverted faculties, and the doctor is indispensable to find and treat the cause of the morbid conditions. Dr. Frederick Peterson, of New York, discussed and opposed "Electricity as a Death Penalty," maintaining that there is a want of harmony between electrothanasia, as it takes place, and the humane ideal of death by electricity as it seems to have been pictured in the minds of the promotors of the new law.

At the evening session a paper was read by Rev. Charles R. Treat, of New York, on "Burial Customs in their Relation to Health," illustrated by the stereopticon, and one by Dr. Charles A. Harvey, also of New York, on "The Best Sanitary Disposition of the Dead." The dangers of the old system of inhumation were pointed out with much force, and those of cremation were also clearly and strongly stated. Dr. Harvey's plan contemplates a process of dessication of the dead in a mausoleum building especially provided for the purpose. The gases of decay are to be drawn off, or allowed to escape through conduits to a centrally located furnace, where they pass through combustion, so that nothing deleterious can escape. This meets the sentimental requirements of affection, guards against contemplation of crime by immediate destruction of the corpse, and prevents injury to the health of the living by any of the results or processes of natural decay.

NOTICE TO CANDIDATES FOR APPOINTMENT IN THE MEDICAL CORPS OF THE ARMY.

AN Army Medical Board will be convened in New York City, New York, October 1, 1889, for the examination of such persons as may be properly invited to present themselves before it, as candidates for appointment in the Medical Corps of the Army.

Application for an invitation should be addressed to the Secretary of War, stating date and place of birth; place and State of permanent residence, and accompanied by certificates, based on personal acquaintance, from at least two persons of repute, as to citizenship, character, and moral habits: testimonials as to professional standing, from the Professors of the Medical College from which the applicant graduated, are also desirable. The candidate must be between twenty-one and twenty-eight years of age, and a graduate from a Regular Medical College, evidence of which, his diploma, must be submitted to the Board.

There are at present nine vacancies in the Medical Corps of the United States Army, in the grade of Assistant Surgeon.

Further information regarding the examinations and their nature, may be obtained by addressing the Surgeon General, United States Army, Washington, D. C.

POSITION IMMEDIATELY FOLLOWING DELIVERY.

DR. CHARLES J. CULLINGWORTH, in his address in "Obstetrics," delivered at the meeting of the Bristol Medical Association, at Leeds, last month, took for his subject, "Some Further Applications of Antiseptic Principles of Midwifery Practice;" and in this connection spoke of the custom of strictly insisting on the maintenance of the horizontal posture for several days after a normal delivery. "For a long time," he says, "I have been disposed to agree with Goodell in doubting the wisdom of this. The question is not by any means a new one. More than a hundred years ago, Charles White, of Manchester, a Fellow of the Royal Society, and one of the most distinguished surgeons ever connected with the Manchester Infirmary, published a remarkable book, with which no doubt many of you are familiar, on the management of pregnant and lying-in women. In the chapter on the prevention of puerperal fever, there occur one or two passages on this subject of posture, which are so striking that I will, with your permission, read them to you: 'In a few hours after delivery, as soon as the patient has had a little rest, she should sit up in bed with a bedgown thrown over her shoulders. If she propose to suckle the child, it should now be laid at her breast whether there be signs of milk or no.' And, again: 'The patient should lie very high with her head and shoulders, and should sit up in bed many times in a day, especially when she takes her food and as often as she suckles her child, and should kneel whenever she has occasion to make water, which should often be done. This frequent upright position is of the utmost consequence and cannot be too much enforced. It prevents the lochia from stagnating, the stools and urine from being too long retained, and promotes the contraction of the uterus, together with that of the abdominal muscles.' How contrary is all this to what is now usually taught! Yet the plan here advocated is merely an application to midwifery practice of the great antiseptic principle of drainage."

FREQUENCY OF CERTAIN PREMONITORY AND AFTER SYMPTOMS IN EPILEPSY.

DR. H. A. HARE contributes to the *University Medical Magazine*, for September, an interesting analysis showing the relative frequency of premonitory and after symptoms in epilepsy, as shown by collecting all these isolated cases reported for various reasons in the journals and thus utilizing a large amount of scattered material heretofore wasted. Of the many thousands of such cases reported in English and

American journals within the past fifty years, only nine hundred and seventy could be found which contained one or more statements of the following points of interest: the side of the body most affected, the frequency of the aura and its character, the occurrence or absence of coma after or during the attack, and the occurrence or non-occurrence of rotation with the direction of rotation. The following results were reached: In only 158 instances out of the 970 cases collected, was anything said concerning the side most affected by the fit, and of those 158 cases it was found that the right side was most affected in seventy-seven instances, and the left was most affected in eighty-one instances, results which agree with the statistics of most other writers.

In respect to the frequency of the aura and its character, it was found that it was noted as present, in some form, in 362 cases out of the entire number, and absent in 138.

The forms of aura most commonly felt were as follows, being arranged in the order of their frequency: —

Tingling	45	"Gastric"	15
Visual	27	Cramps in muscles	11
"Painful"	26	"Olfactory"	11
Twitching	21	"Mental"	8
"Epigastric"	20	Chilliness	7
Headache	16	Faintness	3
"Auditory"	16	"Abdominal"	3
Dizziness	15	Aphasia	3
Numbness	15	Unclassified	44
Disturbed respirations	14		

The occurrence of coma is noted as present in 104 cases, and as absent in 12 cases, but this number is probably incorrect since unconsciousness is a much more common after symptom. It would appear, however, from the history of the cases that the coma in these instances surpassed in its severity the mental hebetude so often seen. In 101 cases only is any statement made as to rotation of the body in the fit, and of these, 49 rotated to the right and 52 to the left; so little difference as to make it appear that both varieties are equally common. It is not attempted to analyze these various symptoms in relation to the total number of cases, because such an attempt was not justifiable owing to the fact, that, through the carelessness of individual reporters any one of these symptoms may have occurred and yet not been recorded. The numbers represent very well, however, in a general way the relative frequency of these symptoms of epilepsy, and as they have been obtained solely from the isolated cases of the journals, they are in no way made up of material already used for analysis.

THE TREATMENT OF IDIOPATHIC CROUP WITH TURPENTINE.

THE *London Medical Recorder* translates from the *Bullétin Général de Thérapeutique* an article by Lewentaner on the use of turpentine in idiopathic croup. For some time past the author has treated his cases of diphtheria by means of the internal administration of rectified essence of turpentine with highly satisfactory results.

CASE I is that of a child, two years of age, in whom the diphtheretic process had extended into the trachea. So critical was her condition that the parents had reluctantly consented to tracheotomy being performed. Before having recourse to this last resort he determined to try Dr. Demelow's suggestion, and he gave the child a teaspoonful of rectified essence of turpentine. In about a quarter of an hour the stertorous respiration became quieter and calmer, and the little patient passed a quiet night, the aphonic cough having quite disappeared. The following day the child was practically convalescent.

CASE II was also that of a little girl, two and one-half years of age, who, when first seen was almost unable to breathe, all the extraordinary muscles of respiration being called into play. Tracheotomy was not practicable, and he therefore gave the same dose of essence of turpentine. The condition of the patient soon became relatively calm, although twenty minutes before the air only passed the larynx with the greatest difficulty. The cough which had been aphonic, became barking. The same evening, although the danger of asphyxia had disappeared, the symptoms of croup were present in all severity, but the parents refused to allow tracheotomy to be performed. Another dose of turpentine was therefore given, and on the following day the more urgent symptoms had disappeared, and all danger seemed to be passed. In two days the patient was quite well. In both these cases a cutaneous eruption followed the administration of the turpentine, but no trace of renal irritation could be perceived.

CASE III. On the seventh day of his illness, this patient, a boy, two years of age, was pale, livid, pulseless, and almost asphyxiated. Stenosis of the larynx was well marked. A dose of turpentine relieved the more pressing symptoms, and on following up the treatment the child gradually recovered, though noisy inspiration persisted for some time afterwards, attributed by the author to a thickening of the laryngeal tissues.

CASE IV. A boy, four years of age, suffering from diphtheria since eight days. This was one case of several, for there was an epidemic of croup at the time, six of which proved fatal. He found the same condition of quasi-asphyxia, with an aphonic cough and cyanosis. A spray of turpentine, eucalyptus, and carbolic acid in alcohol was ordered, and a teaspoonful of the essence given internally. The dose was immediately followed by a violent spasmodic attack of coughing, during which an abundance of false membranes and muco-purulent expectoration was got rid of. The shreds of membrane varied in length from one to three and one-half inches. The next day two other teaspoonfuls of the essence were given, one in the morning and one at night. Thereupon the child began to breathe more freely, took some nourishment and slept all night, except when awakened by the cough. On the second day one more dose was given without any apparent inconvenience. In four days the cure was complete.

OBITUARY. JOHN BOWNE KING, M.D., M.M.S.S.

Dr. King died in Nantucket July 27, 1889, aged eighty-one years, two months. He was born in New York City, and graduated from the College of Physicians and Surgeons in that city, in 1832, and after both hospital and private practice there, came to Nantucket in 1840, where he remained in active practice, with the exception of eleven months in San Francisco, until failing health compelled him to retire, a little over two years ago. He held the office of Medical Examiner from the time of its establishment, and that of Examining Surgeon for Pensions, until obliged to resign both on account of illness; was a Censor of the Massachusetts Medico-Legal Society, and a Trustee of the Massachusetts Agricultural College.

SOCIETY NOTICES.

AMERICAN ORTHOPEDIC ASSOCIATION. — The Third Annual Meeting will be held in Boston, in the building of the Boston Society of Natural History, at the corner of Boylston and Berkeley Streets, September 17, 18 and 19, 1889.

Tuesday, September 17, 1889. — Morning Session, 10 A. M. Business meeting, for the appointing of committees, etc ; 10.30 A. M. Address by the President, Dr. E. H. Bradford, American Orthopedics. Spondylitis after Typhoid Fever, Dr. V. P. Gibney, of New York. The Relation of the Thoracic and Abdominal Wall to the Spinal Column considered with Reference to the Treatment of Anterior-posterior Curvature, Dr. L. A. Weigel, Rochester, (by invitation). Psoas Contraction as a Symptom, Dr. Dillon Brown, New York. Double Congenital Dislocation of the Hip, Dr. Samuel Ketch, New York. Afternoon Session, 3 P. M. A Case of Caries of the Ankle treated Conservatively, Dr. C. C. Foster, Cambridge. A Report of Cases of Caries of the Ankle treated by Excision (with exhibition of patients), Dr. Charles L. Scudder, Boston (by invitation). The Value of Motion in the treatment of Hip Disease, Dr. W. R. Whitehead, Denver. Rest in the Treatment of Hip Joint Disease, Dr. De F. Willard, Philadelphia. Abscesses in Hip Disease, their Prevention, Significance and Treatment, a clinical study, Drs. R. W. Lovett and J. E Goldthwaite, Boston.

Wednesday, September 18, 1889. — The Morning Session, at 10.30 A. M. and the Evening Session at 8.30 P.M , will be devoted to short papers on the treatment of hip disease, after which there will be a general discussion of the subject by the members. It is hoped that in this way the opinion of the Society may be formulated. Subjects will be discussed as follows: Dr. Shaffer, The principles of treatment; Dr. H. L. Taylor, The mechanical treatment; Dr. J. E. Moore, The hip splint: Dr. Steele, The early local treatment; Dr. De F. Willard, The operative treatment; Dr. R. H. Sayre, Excision of the hip; Dr. Ridlon, Fixation and traction in the treatment; Dr. Gibney, Mechanical *vs.* operative treatment. Afternoon Session, 3 P. M The Society will meet in the lecture-room of the out-patient building of the Children's Hospital (Huntington Avenue). Papers will be read on An Experimental Study of Distraction of the Hip Joint, by Dr. E. G. Brackett; An Analysis of twenty-one Cases of Hip Disease treated by the Thomas Splint, by Mr. John H. Huddleston; and The After-Treatment of Hip Disease, by Dr. A. B. Judson. After which orthopedic cases will be shown. Members who desire it will have an opportunity to visit the hospital wards.

Thursday, September 19, 1889. — Morning Session, 10 A. M. The Treatment of Pes Equino Varus, Dr. Henry Ling Taylor, New York. Is Rotary Lateral Curvature of Rachitic Origin? Dr. G. W. Ryan, Cincinnati. A New Exercise in the Treatment of Lateral Curvature of the Spine, Dr. A. J. Steele, St. Louis. 12 o'clock. Business meeting, election of officers, etc. Afternoon Session, 3 P. M. The Treatment by Portative Appliances of Ununited Fracture of the Thigh, Dr. Newton M. Shaffer, New York. Operations upon the Spine for the Relief of Pressure Paralysis, with the report of a case, Drs. Herbert L. Burrell and W. N. Bullard, Boston (by invitation). A Case of Functional Torticollis, probably due to defective eyesight (with exhibition of patient), Dr. R. W. Lovett, Boston. A Case of Congenital Absence of Five Ribs, with resulting Deformities, Dr. Homer Gage, Worcester (by invitation). Exhibition of appliances and apparatus.

R. W. LOVETT, M D., *Secretary and Treasurer*,
113 Boyston Street, Boston.

AMERICAN ACADEMY OF MEDICINE — The Annual Meeting of the Academy, for 1889, will be held at Chicago, Ill., November 13th and 14th, being postponed to that date by authority of the Council.

RICHARD J. DUNGLISON, *Secretary*.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 24, 1889, TO SEPTEMBER 6, 1889.

Leave of absence for one month, with permission to apply through Division Headquarters for an extension of two months, is granted Major BENJAMIN F. POPE, surgeon in U. S Army Par 7, S. O. 54, Department of Texas, August 17, 1889.

By direction of the acting Secretary of War, Major WILLIAM S. TREMAIN, surgeon, now on sick leave of absence at Buffalo, N. Y, will report in person to the commanding general Department of the Missouri for assignment to temporary duty at the post of Fort Leavenworth, Kansas. Par. 4, S. O. 198, A. G. O., August 27, 1889.

PROMOTIONS.

Captain WASHINGTON MATTHEWS, assistant surgeon, to be surgeon with the rank of major, July 10, 1889, vice Town, appointed.

To be assistant surgeons with rank of Captain, after five years' service, in accordance with act of June 23, 1874.

Assistant Surgeon CHARLES B. EWING. July 5, 1889.

Assistant Surgeon WALTER D. MCCAW. August 20. 1889.

By direction of the Secretary of War a Board of medical officers to consist of Colonel EDWARD P. VALLUM, surgeon; Major HENRY MCELDERY, surgeon; Major WASHINGTON MATTHEWS, Surgeon; Captain JAMES C. MERRILL, assistant surgeon; is constituted to meet in New York City on the first day of October, 1889, or as soon thereafter as practicable, for the examination of assistant surgeons for promotion and of candidates for admission into the medical corps of the army. The Board will be governed in its proceedings by such instructions as it may receive from the surgeon general. Par. 1, S. O. 205, A. G. O. September 2, 1889.

Leave of absence for two months on surgeon's certificate of disability, is hereby granted Major P. J. A. CLEARY, surgeon U. S. Army. S. O 59, Headquarters Division of the Pacific. San Francisco, Cal., August 31, 1889.

The resignation of Captain Joseph Y. Porter, assistant surgeon, has been accepted by the President to take effect August 29, 1889. Par. 11, S. O. 200, Headquarters of the Army. A. G. O. August 29, 1889.

Leave of absence for twenty-one days is granted Captain CHARLES B. EWING, assistant surgeon, to commence on or about September 21, 1889, provided that at that time the post surgeon now on leave has returned to duty. Par. 5, S. O. 201, Headquarters Division of the Atlantic. Governor's Island, N. Y., September 4, 1889.

Leave of absence for fifteen days is granted First Lieutenant W. B. BANISTER, assistant surgeon. Par. 2, S. O. 82, Headquarters Department of Arizona. Los Angeles, Cal., August 25, 1889.

The garrisons of Fort Laramie, Wyoming, Fort Hays, Kansas, and Fort Lyon, Colorado, will be withdrawn, and the posts named will be abandoned as soon as it can be done with due regard to economy. G. O. 69, A. G. O. August 31, 1889.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING SEPTEMBER 7, 1889.

F. S. NASH, past assistant surgeon, detached from the "Dale" and ordered to duty in the Bureau of Medicine and Surgery.

A. C. H. RUSSELL, past assistant surgeon ordered to naval hospital, "Yokohama," per steamer of September 28th.

C H. H. HALL, past assistant surgeon, detached from naval hospital, "Yokohama," on reporting of relief, and return home.

S. S. WHITE, assistant surgeon, detached from naval hospital, New York, and ordered to "Minnesota."

E. P. STONE, assistant surgeon, detached from the "Minnesota." and wait orders.

P. H. BRYANT, assistant surgeon, detached from the "Ajax," and ordered to naval hospital, Norfolk, Va.

A. R. WENTWORTH, assistant surgeon, detached from naval hospital, Norfolk, Va., and await orders.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTJES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING AUGUST 24, 1889.

LONG, W. H., surgeon. To proceed to Gallipolis, Ohio, as inspector. August 7, 1889.

WHITE, J. H., passed assistant surgeon. Granted leave of absence for thirty days, on account of wound. August 16, 1889.

CONDICT, A. W., assistant surgeon. Detached from Revenue Bark "Chase," and ordered to Louisville, Ky., for temporary duty. August 19, 1889.

GROENEVELT, J. F., assistant surgeon. Ordered to South Atlantic Quarantine Station for temporary duty. August 8, 1889.

BOOKS AND PAMPHLETS RECEIVED.

Thirteenth Annual Announcement of Ensworth Medical College and Hospital, St. Joseph, Mo. Session 1889-90.

Thirtieth Annual Announcement and Catalogue of the Hahnemann Medical College and Hospital, of Chicago, Ill. 1889–90.

Electrical Distribution of Light, Heat and Power. With partial List of Deaths from Electric Lighting Circuits. New York. 1889.

Address.

THE PROGRESS OF MEDICINE DURING THE LAST FIFTY YEARS.[1]

BY FRANCIS MINOT,
President of the Association of American Physicians.

If we consider the progress which medical science has made during the past fifty years, and its position at the present day, we are led to hope that the time is not far distant when the healing art will approximate in certainty to the exact sciences. Not many years ago, for example, it seemed impossible that a correct diagnosis of the principal structural diseases of the brain and spinal cord could ever be attained; and yet we are now almost as familiar with their characteristic symptoms, and with the nature and anatomical situation of their lesions, as with those of the lungs, the heart or the pleura. The twin departments of physiology and pathology (the former was born almost within the memory of some of us) have made immense strides, and, along with improved methods of clinical observation and research, have aided more than anything else in the advancement of our knowledge of disease and its treatment during the past half century. Bacteriology has revolutionized our notions of the causes and nature of many diseases, and of their proper management. A great amount of useless and pernicious medication has been abandoned, while the number of valuable remedies has been increased. The principle of prevention is advancing in proportion to our increased knowledge of the causes of disease, and hygiene has become an important branch of medical education. Even in tuberculosis, the most wide-spread and fatal of maladies, the results of prophylactic treatment, founded in part on the great discovery of Koch, are found to be most encouraging; and it is not unreasonable to hope that the disease may in time become as controllable as is small-pox at the present day.

Many other recent advances in medicine readily occur to us. I need only mention the progress in State medicine, in public hygiene, in the construction of hospitals, in our acquaintance with the laws of climatic treatment of disease; passing by many others which the limited time at my disposal prevents me from noticing. In no department of medicine, however, has development been more conspicuous than in that of teaching. Formerly, good teachers were rare, and students were compelled to acquire what knowledge they could chiefly by listening to didactic lectures. In my day there was but one teacher in clinical medicine in Harvard Medical School, and he could give but little time to it, being at the same time professor of materia medica; whereas now clinical teaching has to a great extent supplanted didactic lectures in all medical schools. New departments for the study of various specialities have been created, and provided with competent teachers and well-equipped laboratories, and it cannot be long before a full course of at least four years' study will be required of every applicant for the degree of doctor of medicine.

Did time allow, it would be interesting to study the causes of this great advance in medical science, but I can barely allude to them. In many respects they are the same as in the case of other sciences, both physical and moral. Each step forward of one helps the growth of others. Medicine is almost as much indebted for the position it now holds to biology, to chemistry and other branches of physical science, and even to mechanical art, as to clinical observation and pathology. Electricity puts us in touch with the whole civilized world, and every new discovery in science and art is immediately announced from one hemisphere to the other. Communication between distant regions is abridged by railroads and steamships; and scientists whose homes are thousands of miles apart can come together with comparative ease, for the interchange of knowledge. We must, indeed, ascribe to the more frequent professional intercourse which we enjoy a prominent influence on the growth of medical science, as of science in general. In small communities physicians do not often meet for the discussion of medical subjects, and stagnation of ideas is apt to arise from the lack of diffusion of personal knowledge; but when large numbers are gathered together from distant parts, differences of experience and observation give rise to discussion and to the development of new ideas. We find, for instance, that diseases may vary in clinical aspect, in severity, and in methods of efficient treatment, according to geographical situation, climate, elevation, race and modes of life. Some are more or less strictly confined to certain regions, and our knowledge of them must be obtained from observers living in those regions, or visiting them. The treatment of disease, both general and special, often varies much in different countries and in different parts of the same country. In some it is active, including a large amount of medication; in others it is more passive, being directed rather to the condition of the patient and to the special symptoms which he exhibits, than to the disease itself. Certain wide-spread diseases, specific in their nature and self-limited in duration, are found to be but little influenced in their mortality either by geographical locality or by different and opposite modes of treatment; while, on the other hand, age, constitution, habits, and complications play a much more important part in the result. This is strikingly shown in the various papers on the mortality of pneumonia which have appeared in different medical journals during the past year.

It is not easy to overrate the great influence of the medical press in elevating the standard of the profession, and in the diffusion of scientific knowledge in all parts of the world, by the publication of original articles, clinical and other lectures, reports of interesting and instructive cases, and proceedings of societies and conventions. Thousands of practitioners who are unable to leave their homes are thus brought into communication with the highest authorities in medicine, and can avail themselves of the most recent advances of medical science.

Finally, we must recognize as one of the great advantages of medical conventions the privilege of becoming personally acquainted with men from all parts of our country whom we have hitherto known only by reputation, or through their writings. In this way the profession is more closely drawn together, sectional prejudices are allayed, harmony of ideas on the subject of medical improvement is promoted, and the foundation is laid of enduring and delightful friendships.

The organization of this Association is peculiarly adapted to aid the progress of medical science. It

[1] The President's Address before the Association of American Physicians, delivered at Washington, Wednesday, September 18, 1889.

represents no one section of our country, but includes practitioners from all parts of the United States and Canada, whose experience, observation, knowledge, and ability are brought together for comparison and for mutual instruction. The programme for the present session includes many subjects of interest and importance, and its length warns me that I must no longer trespass on your time.

Original Articles.

SCIENTIFIC WORK BY ALIENISTS.

BY F. B. STEPHENSON, M.D.,
Surgeon, United States Navy, A. A. S.

IN a recent issue of the *Nineteenth Century* is published, under the title "Lunatics as Patients, not Prisoners," a semi-professional article by John Batty Tuke. A fair amount of expert knowledge is necessary to the adequate appreciation of his remarks: we may also bear in mind that he is at the head of a private asylum for insane.

From the above paper it appears that in England, the taxpayer, seeing a steady increase of pauper lunacy, is inclined to think the millions of money furnished for the arrest of such disease not judiciously expended; that the public look fruitlessly for any manifest indication that the specialty which professes the treatment of insanity has kept abreast in the onward march of science; that grave and deep-seated faults underlie the system of management; a doubt arising as to whether mere philanthropy has not absorbed the pabulum which should have given life and strength to really kind science. The ultimate object of the numerous establishments — the greatest good, that is, cure, of the insane — has not been obtained, because the best methods have not been adopted. While it seems ungracious to demonstrate the failure, in any degree, of philanthropic schemes, yet, if we are to progress, experience should be bold in criticism. Although it is a primary duty of the State to protect, affording refuge is not the highest function of an asylum. To quote the author, "The structure and arrangement of any one of our pauper asylums," with "the constitution and duties of its medical staffs," show that the "organization was begun on the motive of protection and under the psychological (non-modifiable by treatment [?]) theory of insanity." "But what has been done for the disease of the brain? We seek in vain in our asylums for any evidence of systematic inquiry" and treatment based on modern notions of cerebral physiology. We find, indeed, chapels, ball-rooms, cricket-grounds, but no hospital or laboratory for psycho-pathologic research. To copy, again, his words, "Committees have but little sympathy with the scientific view. So far is this the case that I have known candidates for appointments objected to on the ground that they had scientific proclivities, and had no knowledge of farming." This original plan has undergone little if any modification down to the present day, while a century of observation has been lost and hundreds of misdirected lives of good men wasted or frittered away. If this be thought strong language, compare the work done since 1850, regarding the pathology of the brain and spinal cord, with what has been accomplished by specialists in lunacy. Save a few recent sporadic efforts, the veteran Calmeil only has given to the world productions worthy consideration as scientific in the almost future branch, psychiatric medicine: for, as yet, treatment is entirely empirical, depending mainly on good hygiene and personal experience.

Dr. Tuke makes pertinent recommendations as to appropriate disposition, style, and expenditure in architecture; changes in supervisional and medical duties; furnishing apparatus for observing, treating, and teaching; and the benefits which will therefrom ultimately reach the public. Physicians in asylums should be allowed to fulfil the proper duties of their office, but not be required to do the custodial routine service for which properly-trained attendants are quite competent. More cures might, in such conditions, be expected, and time secured for original investigation, progress, tending toward evolution of a rational system of treatment.

Concerning alleged difference in principles of management by the English and Scottish, he states that such does not exist, unless it be in the point of administration, efficient supervision over a limited area being the practice in the northern realm. Of bills lately proposed for legislation he strongly combats those which (besides other defects, some of them doubtless due to their being drawn up by lawyers only) permit especial privileges to existing private asylums.

The questions above treated, while not altogether new are of such importance that they may well be brought repeatedly to the attention of a public interested in both the welfare of the individual now needing care, and the scientific investigation that will inure to better guidance of future sufferers from enfeebled or disordered mind. Despite yet existing impediments to the cure of acute cases, and embarrassments in the care of the chronic insane abroad (which evils are apt to become of great moment in this developing nationality), recent literature upon the condition of lunatics in the Old World inclines us to have a somewhat more optimistic opinion than that given in Dr. Tuke's paper. The limits of this review, however, compel us to restrict the present survey rather to facts and projects of our own country.

In America, during recent years, the great number of applications for admission to asylums, and the pressure to provide accommodation for inmates put upon those in charge of administration, have hitherto practically prevented extended scientific work. It has been rather a period of asylum-hospital construction. The capable superintendent is presupposed to possess professional and moral qualifications of a high order, being charged with delicate and responsible duties, in the proper performance of which every citizen of the State is deeply interested. Though illumined by the philosophic spirit, and enthusiastic with faith in the gospel of science, he has been, therefore, necessarily almost exclusively occupied with the business of direction; has not had time to give his personal oversight to details of original research, or to use his own fingers in manipulation of the microscope and other appliances: yet he is abundantly able to indicate what course skilled observers may wisely follow in old or in newly-found fields of work and experiment, and to lay out the tasks with which others can be productively employed.

Granting that European institutions are, perhaps, in some ways, more fully equipped as regards hospital

adjustments (mechanism of moral treatment), and more fruitful in publications of value, a careful reader of current literature *in re* may notice that, in this country specialists in lunacy are aroused, and are doing creditable work for science (*V. inter alia, The American Journal of Psychology* and *The American Journal of Insanity*); while at the same time actively engaged in details of administration and the psychic treatment of their patients in the line of occupation and recreation: which latter is often quite as important in remedial effects as more formal schematic or technical endeavor.

Of by no means secondary value in this connection are the physical conditions allowing the patient to be put under beneficent influences with respect not only to the outside world, but also with his companion-inmates mentally sick; conditions that may be supplied by a "flexible hospital-asylum architecture." There seems to be a tendency to limit unduly the meaning of the expression, "scientific work." As Sir James Paget says, "The sick-room is a laboratory with its crucial experiments:" the same is due of the other physical adaptations before mentioned. In the latest-formed and best colleges for higher education (besides provisions removing the thralls of poverty from young talent), thorough preparation, complete facilities, etc., exist, or are being perfected, for the study of psychology, with a comprehensive biology. These are fields of research wherein progress in knowledge, involving promise of future scientific product and consequent practical benefit, now appears most likely. Great stress is also laid upon the importance of "leisure and tranquility" for the accomplishment of veritable, serviceable culture. Considering these things, one is led to think that, if such conditions are recognized as necessary to the normal functions of the average healthy brain, how much more are they needed for arrest or cure, through guidance, of morbid action in one weak and diseased. And this is as truly "scientific work" as the publishing of formal treatises. Our Scottish *confrère* need not fear contradiction when he writes: "What every asylum requires in order to become a truly curative institution is a hospital for the treatment of recent and acute cases, separate and distinct from the main establishment, to which each patient should be consigned on admission." May we suggest, moreover, that the feature of separatism should form the central idea of any hospital-asylum plan, and not be looked upon as of secondary moment? In regard to the bearing of the study of long-seated disease on the cure of insanity, however, he appears to be of an opinion different from that of the critic, Frederick Bryan, who thinks that the close observation of chronic symptoms and subsequent morbid conditions are just as important as the study of recent cases for the amelioration of acute manifestations by treatment; and, indeed, may give far more valuable results (to appear, we may presume, in the better understanding of normal and pathologic psychology). The present apparent hopelessness of cure in instances of confirmed malady should be a stimulus instead of a bar to its careful investigation by men of science. "The cure of the curable insane is one thing: the care and treatment of the insane generally is another. The former is purely a medical question: the latter a social one." Both have undergone, and are susceptible of further great modification for the better, through the practical application of results due to systematic research and experiment.

Unquestionably great progress has, within the last decade, been made in the United States, for the public care of the insane. Though also much improved, the defects of existent arrangements for private care of the insane are recognized, and there is already evidence that an adequate provision therefor will be made in the early future. The amount of change, quietly made, is equivalent to almost a revolution. The constituent *motifs* of the hoped-for resultant harmony may be stated: the creation of trained attendants, faithful, and humanely sympathetic; better systems of classification; allotment of more space and personal liberty; segregation, and greater individualization of treatment; limited number of patients; improved surroundings; increased employment and occupation, with skilfully-directed incentives to action. Institutions for the chronically insane, says Dr. Chapin (the eminent American alienist, in his recent annual address), being brought under the recent comprehensive policy, we should make a further advance toward the best treatment of acute cases.

Some forms of insanity seem to consist of outbursts of psychic force; and in these tonic treatment appears effective: patients with exhaustive mania assimilate several times the average quantity of aliment. Materia Medica furnishes new remedies whose powers are being tested. "Therapeutic suggestion" is not forgotten. Mortality from acute forms has declined; and if but a small proportion of recoveries appear in various returns, it should be borne in mind that such reports include a large number of chronic cases. "Commendable work is being done in the better preparation and record of cases, and the microscopic sections; also, by aid of photography." Yet, as Dr. Savage remarks: "There is still a deep ditch of ignorance between us and the true pathology (and for that matter, physiology) of mind; and this ditch has to be filled by those who sacrifice their time and their energies in steady, unremunerative labor." The New Psychology may help to show the way to solve some of the many important problems that arise to confront alienists in their daily work.

As an example of results due to the spirit animating advanced workers in these matters, we may refer to what is being done by one of the New England asylums within our own knowledge. The institution in mind, the McLean Asylum, has a competent official (termed, perhaps, psycho-pathologist) who is allowed to use his entire time for clinical (psychic and physical) observations, to be later compared with gross and microscopic anatomical appearances. This gentleman, having received a thorough general professional education, enjoyed the advantages of training in the advanced schools of the old world, and being appointed on a salary sufficient for a reasonable living, enters upon his life-career. During three months of each year he is granted leave of absence, so that rest and visits to other centres of activity may better enable him to accomplish, in his own line of duty, something of value. A correspondingly appropriate laboratory is in preparation. The natural outcome of such a plan will be to maintain an intelligent continuity of strictly scientific work, to which other officers of the institution will contribute (although for the greater part of their time immediately occupied with clinical detail), and by which they will be stimulated to more critically exact investigation of psychologic problems.

Another model feature of this refuge for the insane

is a school wherein nurses are taught, at first, duties in the care of any sick person; and, progressively receive instruction regarding the special skill requisite for those who take beneficent charge (physical and psychological) of the mentally ill. They are also trained in the practical application to therapeutic uses, by newest scientific methods, of systematic physical exercise (an enlargement of the massage principle), adapting it to the special need of each patient, as exemplified in a lately-completed gymnasium. "The success of asylum management and of hospital treatment is without doubt largely dependent on maintaining a good corps of intelligent and faithful attendants." By this mode of teaching, of preparation for a life-work (one highly honorable), the advantage of the learner and benefit of the general public in want of skilled service, are alike secured. The indirect good of such enlightenment upon the prosperity of the Commonwealth is not unworthy consideration by our State and municipal authorities. This new departure exerts an influence not limited by territoral confines.

While much energy is expended, especially by older men, on the urgent providing for the present physical well-being of the patient, as a matter of primary necessity, nevertheless, an observing, active alienist may see that the modern scientific touch has awakened the spirit of Young America to bend its nascent energies toward earnest, methodic effort. If, as yet, pathology has furnished comparatively little of use in prophylaxis or therapeusis, is this sufficient reason for decrying research in directions warranted by positive advances in alienism, as well as by excellent results in other fields of thought and inquiry? Experiences accumulated from year to year make just our hope in a future full of promise.

These expert men must be obtained in order that the *matériel* be best utilized, both for the direct good of individuals and their future betterment through progress in knowledge, that is, "scientific work." Students (aspirant or actual) need only relief from the burden of self-support to allow them free course in the laborious, persistent endeavor toward which a laudable ambition urges. The doing of creditable work requires steady, reliable aid on the part of those in real, proximate control; and by those who can supply means necessary to keep an active, educated man in physical, mental, and moral health, such as food, exercise, rest and recreation, encouragement, criticism, and judicious approval. As an able and conscientious alienist physician has lately written: "The hope of advancement in the care and cure of the insane lies largely in the perfection of the appliances (and, may we add, a trained *personnel?*) with which we have to work, both for promoting the present welfare of the sick and for the prosecution of scientific inquiry."

The Government (possibly through the agency of the Smithsonian Institution) might serve the general public by forming a "repository of hospital plans;" those in charge, besides having other pertinent duties, being empowered to secure information from foreign sources, "which ought to be accessible, and would prove instructive to medical men, commissions, and State officials." One immediate effect of this knowledge should be the much-needed improvement in the condition of the insane now in our county almshouses; although mere "politics" yet seem to have an undue influence as to the control of such "homes" for the poor and friendless. So long as the permanence of officials, lay or medical, at the post of duty, depends upon the current local election, we cannot expect either good performance of ordinary executive functions or professional results of scientific value: mediocrity, even, is hardly to be anticipated. We commend for study the system of dealing with the insane in county asylums practised in Wisconsin.

Letchworth's admirable book, "The Insane in Foreign Countries," contains succinct data upon the excellent methods of hoary antiquity, when psychology was recognized as a department of medical study. It is an historic summary, and a vivid pen-picture, by an experienced expert, of the contemporary status of European remedial and custodial measures in lunacy. This timely volume affords much of value for those of our citizens occupying positions to influence public opinion toward a wise care of those whom proper and prompt action may save from permanent disease. The author prophetically says: "In America, where, from a variety of causes, there is so much mental activity, and where a condition of great prosperity attracts the surplus population of Europe, there are obvious reasons why the various problems relating to insanity should receive most careful attention."

ESCHAROTICS IN THE TREATMENT OF MALIGNANT DISEASE.[1]

BY JOHN C. MUNRO, M.D., BOSTON.

IN reviewing the history of escharotics in the treatment of cancer, one meets on the one hand with assertion, honesty and implicit faith; on the other with denial, dishonesty and bigotry. Each particular drug has a champion ready to defend it by fair means or by foul, and to give a just verdict to the claims of each champion is by no means an easy task.

One main fact, however, must be maintained here from the very beginning: escharotics are not best and safest for the treatment of cancer in even a fair proportion of cases. The knife or the sharp spoon stand preëminently *the* method of treatment, and it will stand so until some specific is finally discovered; but there are a small number of cases where the use of the knife is impracticable or impossible, or where a fear of its use makes it impracticable; in these, caustics, if any treatment is possible, can and ought to be used.

With regard to immunity from recurrence after removal by caustics there are no data in all history that warrant one to conclude in favor of caustics over the knife; without question the chances are just as good and just as bad in either case, *cæteris paribus*.

The best observers are furthermore agreed that where the treatment is undertaken it must be steadily and vigorously pushed, not done in a half-hearted manner; and by observing proper precautions there should be no especial danger.

Individual cases and statistics will be avoided in what follows; a great many have been carefully analyzed, but they are of such a nature that their value in deciding, absolutely, any question, is almost *nil*, and it has seemed best to give only general conclusions. The various important caustics will be considered in order, and then an outline of the history of their uses, together with that of the most famous men (both honest and dishonest) connected with them.

Next to the actual cautery, which is painful, limited

[1] Read at the annual meeting of the Massachusetts Medical Society, June 12, 1889.

in its action, often more dreaded than the knife, and useful only in a small proportion of cases, the strongest escharotics are the mineral acids. Of these nitric acid is most generally used. It is energetic but difficult to manage, so that ordinarily its employment is limited to the destruction of the epidermis over tumors for the subsequent action of other escharotics, or to the application in small superficial malignant growths. Rubbed up with charpie to a gelatinous mass it is more under the control of the surgeon.

Sulphuric acid mixed with some substance like saffron, lampblack, asbestos or sulphate of zinc, was considerably used at one time; it makes a dry, black crust that is rapidly cast off, but it seems to be inferior to the alkaline caustics. Hydrochloric acid and nitro-hydrochloric acid are of less value than nitric acid.

Acetic acid has been used mainly in subcutaneous injections into the tumor. This method of using it, though probably not original with Broadbent, was strongly advocated by him in 1866. He was led to its use from noticing the effect of the acid on tissues under the microscope; that is, a shrivelling up of the cancer cells without coagulation of the albumen. In 1867, Moore showed before the London Pathological Society a cancerous gland that had been injected, during life, with the acid, one part to three parts water. The gland consisted of a thin shell with contents of a light brown inodorous pulp containing pools of free oil, while on microscopical examination very few cancer-cells were to be seen. When successful, apparently a sloughing of the tumor takes place with discharge of the cancer elements, leaving a clean granulation wound behind. Tillaux, Maisonneuve and Langdon, after trial, gave up the method as dangerous and inefficient. Of late years, however, Gies, Duplouy, and a few others, have reported marked successes; but it is a method not destined to become very popular. It is intensely painful, and its use is followed by a more or less prolonged discharge.

Chromic acid is self-limiting in its action, as it is rendered inert by reduction to an oxide in the process of destruction of the tissues. It is very thorough, does not cause very much pain unless impure; and there must be cases where its employment would be valuable, care being taken to prevent toxic effects or a too deep penetration of the tissues.

Osmic, pyrogallic, salicylic and citric acids do not offer claims worthy of consideration, though the latter is said by Brandini and many others to give relief from the intense pain that often accompanies morbid growths.

Carbolic acid (though not belonging in this series) has been used with iodine in uterine cancer by Battey and others, who report good results. Its usefulness must, however, be very limited.

Chloride of zinc, the best of any of the metallic chlorides, and perhaps most useful of any of the potential caustics, has been employed in cancerous growths for about one hundred and fifty years. All pastes containing this agent are, practically, modifications of the formulæ of Canquoin. Velpeau, Maisonneuve, and a host of others, have highly praised its use; while in our own time we find Butlin writing strongly in its favor. Apparently it causes more pain than its rival arsenic, yet it is not only more thorough in its effects, but hæmostatic besides. It may be used in varying strengths with some inert substance or with some other caustic, like corrosive sublimate, arsenic, chloride of antimony, etc. Maisonneuve and Girouard used it rolled out into small sticks or arrows which were inserted through punctures in the sound skin into the tumor itself. It has also been used to a small extent for subcutaneous injection in dilute solution. It forms a dry, white seal that separates in about ten days spontaneously, or in less time if a poultice is used. The surrounding parts may be protected by some greasy substance, and if necessary, the slough can be scarified down to the underlying morbid tissues, and the zinc reapplied until the entire growth is cauterized.

Sulphate of zinc, in the form of anhydrous powder, is highly recommended by Stephen Smith. He first penetrates the skin with a mixture of sulphuric acid and the salt, and then, after leaving the zinc alone on the growth for three or four hours, any liquid residue is removed and a poultice applied, the slough separating in five or six days. Simpson, of Edinburgh, also used this agent with good results.

The following acid or neutral caustics may be dismissed with a brief mention. The use of any of them is restricted, and an extended discussion as to their merits or demerits would be out of place.

Sulphate of copper, dating its use as a caustic from the time of Galen, is mild and but rarely used now.

Corrosive sublimate is very poisonous and of limited value.

Chloride of iron acts very slowly and hardly like an escharotic.

Acid nitrate of mercury may be of service in ulcerated growths where a prolonged action is not required.

Nitrate of silver is of limited value, and permanganate of potash is even less escharotic in its action.

Chlorate of potash, used by Bergeron, Blondeau, and later by Burow, is applied in powder to open cancers, and although it can hardly be said to have an escharotic action, it causes a shrinkage of the tumor besides an absorption of infiltration and a diminution of secretion.

Arsenic (arsenious acid) stands with chloride of zinc and caustic potash at the head of useful escharotics. The names and varieties of pastes that contain this agent as a basis are almost without number, but the simplest are undoubtedly the best. The use of the drug in cancer dates from the earliest times, and by many modern surgeons it is preferable to any other caustic. Some even claim for it a special action upon cancerous tissue, whether administered internally or externally. When properly applied it is harmless, less painful than zinc chloride, and easily managed. Manec investigated about one hundred and fifty cases treated by Frère Côme's paste, and was led to ascribe to the drug an elective action; he found that elimination takes place in five to eight days, and hence advised that the applications be made nine days apart, but if any general, systemic effort is desired this would not seem necessary. Subcutaneous injection has been tried, but with poor results.

In 1874 the younger Marsden, who with his father was surgeon to the London Cancer Hospital, published a treatise founded on statistics of a period covering twenty-two years, and including about six thousand cases, and corroborated in great part by the resident physician, Dr. Crombie. He used a paste for the most part consisting of one-third mucilage of acacia and two-thirds arsenic; he does not deny that a return of the disease may take place, but the treatment can be

applied to so many cases that are out of reach of the knife that it is wrong in his eyes to entirely disregard a therapeutic agent of so great value.

His method, which is very simple, and has the merit of having been extensively tried, is briefly as follows: Spread the surface of the cancer, — not over one square inch, however, at a time, — with the paste; over this apply dry lint, any superabundant paste being removed after a space of ten minutes. In twenty-four hours there will be swelling and redness of the surrounding parts, and a drawing pain lasting one or two days. At the end of two or three days a poultice may be constantly applied, a distinct line of demarcation being seen with ulceration, and a fissure separating the slough from the healthy tissue. In six to thirty days, according to size, the slough comes away, leaving a healthy cavity. In some cases it is necessary to apply the paste every second or third day, until the desired effect is obtained, but no poultice should be applied until after the last application of paste, and no paste should be applied after the line of demarcation is formed. From this it is easily seen how partial or even bad results may be obtained from an unskilful use of the agent.

Helmkampff, in an extended article, advises that the strength of the arsenic be not over one-fifth or one-sixth that of the paste, lest too much inflammation be excited.

The extravagant claim made by some that return after destruction of a cancer by arsenic in particular is less liable to occur than after the use of other caustics or of the knife, is not borne out by careful observers.

Caustic potash is a well-known and efficient escharotic. With lime (equal parts) it forms Vienna paste; melted and run into leaden moulds it is called Filhos' caustic. Both forms are used considerably in France. Vienna paste is more manageable than the potassa alone, as it is less powerful and does not deliquesce nor run so much. It is rapid in its action, however, and aggressive, and for these reasons the milder arsenic is preferred by many.

Alveloz (aveloz), the acrid juice of one of the Euphorbiaciæ growing in northern Brazil, has been used by Janvrin in uterine cancer, and a number of good results reported. He prefers it to any other caustic in early cases, while even in those far advanced it is palliative and diminishes pain; others beside Janvrin have also derived benefit from its use.

A short glance at the history of escharotics and of the men that have marked separate eras, either by the benefit or harm that they have contributed, will help to show perhaps some of the merits that really belong to this much-abused subject.

In the writings of Hippocrates we find mention of the use of desiccants and caustics for the purpose of producing a superficial slough and of removing the morbid parts in indolent and malignant ulcers. One of his applications contained hellebore, flakes of copper, arsenic and cantharides, and it seems not improbable that some of the ulcers he speaks of were epithelial.

Galen distinctly advises such caustics as sulphide of copper, tersulphide of arsenic and quicklime, and in speaking of excision of mammery cancer he says that, if it is intended to cauterize the remaining roots of the cancer, care must be exercised when this occurs near important parts.

Following Galen, but after a long lapse of years, we find Guido "lavish of his encomiums on arsenic;" soon after come writers such as Fallopius, Ossenius, Penotus and Borellus, each with some particular preparation containing the same caustic. But it is not until the latter part of the sixteenth century that the use of arsenic as a cancer-caustic is at all systematized and placed on a firm footing. At this time Fuchs practised with great success in England, Germany and Poland; his powder, called by one writer *Pulvis Benedictus*, was made up of a white arsenic ground to a fine powder, brandy (*aqua vitæ*), a species of wormseed dried in an exposed place, and refined (*splendidi*) chimney-soot. All this was finely ground together and kept in a well-covered glass vessel a year before being used.

For nearly two hundred years little progress was made. It was a prosperous time for quacks and home remedies. Among the latter is the Earl of Arundel's recipe, said to have been given him in 1638 by one of a family of cancer-curers. Later, in 1714, we find the MS. recipe belonging to a family named Pains, with this marginal note: "Used by my Father & Grandfather & Brothers and known as a thing excellent by long Practice in our Family of Pains." Both of these recipes relied upon arsenic for their activity.

In the middle of the eighteenth century the famous Plunkett flourished. He laid great stress on the extraction of cancer-roots, and his recipe, which is also said to have descended from his ancestors, is interesting as given by Sir Spencer Wells: —

R Crowsfoot which grows on low ground, one handful.
Dog fennell, three sprigs. } well pounded.
Crude brimstone, three middling thimblefuls.
White arsenic, same quantity. All incorporated well in a mortar, then made up into small balls the size of nutmegs, and dried in the sun.

He sold the recipe to Guy, a contemporary, and it is also at this period and a little later that we hear of Martin, Pope, the younger Guy and Davidson — the latter enjoying a considerable reputation in our own State.

It remained for Frére Côme to crystallize the various and blundering methods of using arsenic in malignant growths. His paste originally containing red sulphide of mercury, charcoal and dragon's blood, beside white arsenic, was the base of all future arsenical pastes; it was simplified later and adopted into the French Codex. Very many cases were treated by Côme and other enthusiasts, such as Rousselot, Dubois, Dupuytren, Maisonneuve and Manec.

In 1834, Canquoin communicated to the Royal Academy at Paris the results in a number of cases treated by himself since 1824, with pastes of which chloride of zinc was the basis. Four years later appeared a complete exposé of his treatment, and although there is no question as to the virtue in his various pastes, the extravagant claims made by him must be taken with a good deal of latitude.

In 1847, Filhos recommended, especially in uterine cancer, the caustic that bears his name; that is, potassa and lime melted and run into moulds. This caustic, much prized in France for awhile, is a slight improvement over the time-honored Vienna paste.

Eight years later, Landolfi, Surgeon-in-chief to the Sicilian army, made strong claims for pastes containing the chlorides of bromine, zinc, gold and antimony, in various degrees of strength; he considered the gold as a specific in encephaloid cancer, and internally he gave

chloride of bromine, fennel and hemlock. Many cases were treated under the diagnosis and attendance of Rokitansky, Meckel and others, but a commission being appointed to investigate the method, decided that it was only a modification of that of Canquoin, besides being more painful and not so efficacious.

At this same time the notorious Dr. Fell, an American practising in England, appeared before the public. He claimed that his treatment, imparted to him by the Indians, was new and depended on Puccoon (blood root) for its activity; it soon came out, however, that he used chloride of zinc, but he made such glaringly false statements and used the caustic so injudiciously that he brought a storm of wrath upon himself from educated, conservative practitioners. The accounts that the latter give of patients that had been through Fell's hands are simply horrible in many cases; in fact they remind one strongly of that which takes place under quackery at the present day and in our own State.

One recalls the story of the Emperor Gallienus cured of a sciatica after undergoing a thousand painful experiments: "Take," he said to his physician, "take, Fabatus, two thousand sesterces, but withal, be informed I give them not for curing my sciatica, but that thou mayest never cure me again."

Meanwhile, in 1859, one of the most notorious of all quacks was holding sway in Paris. This was the so-called "Black Doctor," a negro by the name of Vriés. He soon gained a large clinic among the laity, and in order to give him a fair trial Velpeau placed sixteen cases under his entire charge, at Charité. At the end of three months, Velpeau, who had closely watched the cases, reported to the Academy, mainly as follows: No cases had been cured; the composition of the specific varied, it being aloes or iodine in England, but an inert vegetable powder of some kind in Paris; Vriés had no idea of cancer, nor of examining a patient; no promises had been fulfilled, and he had made false statements to the papers for publication. The patients were taken from his care, and later he was imprisoned, but it is needless to say that he had many devoted believers and followers.

A year after this another imposter was claiming attention in England: the Rev. Hugh Reed, whose treatment consisted in the use of some gas, probably chlorine, together with some internal medication that brought on salivation. At Reed's own request, Sir Spencer Wells investigated a number of his patients. In six he found no benefit from treatment, and in three others there was no cancer.

In 1870, another fraud, Buchanan, appeared on the scene. He claimed to use chlorate of carbon, which he sold for five dollars per pound, but which later proved to be chlorate of potash.

It is needless to name any of the quacks that have flourished since this date, while the names of the few men that have helped from higher motives, to keep this method of treatment at its proper level, can be found in any modern text-book of surgery.

Of the former class all practitioners know at least a few by name and deed. A more or less intimate knowledge of some of the most notorious in this city serves only to emphasize the one great fact that where so-called quacks do deserve credit in one case, there are many where they cannot be censured too severely. They are grossly ignorant of the nature of cancer, and, what is more surprising, of the action of the drugs that they use. They look upon the regular profession as bigoted and subservient to the traditions of European schools, and yet I have failed to hear one of them show the least intelligence on subjects in which they claim to be specialists. They do cure, so far as any one can cure, cancer, — that is willingly granted. When, however, one notorious swindler says that he has cured hundreds of cases, while another, his friend and supporter too, affirms emphatically and confidentially that the former has never cured a single case, but relies on defrauding and cheating a fellow quack for his own aggrandizement, it is difficult to make up one's mind that there is truth in any of their assertions. In fact, the healthiest sign, to be seen now, is the uncompromising condemnation that most quacks hold toward others of their kind. I have had too many proofs of this to leave any doubt in my mind of the fact.

An intelligent, skilful use of escharotics, on the other hand, is capable of doing a great deal of good in cases not suitable for excision; it will also serve to bring into good repute a method of treatment ignorantly employed by a class of men and women that has only selfish, brutal ends in view.

Let this be emphasized by a quotation from Butlin, who speaks from a considerable experience. He says: "I would urge that it (the caustic) be used far more frequently in surgical practice than it hitherto has been. I do not know whether it furnishes a better guarantee against recurrence, . . . but it affords quite as good a guarantee, and I fully believe that its use is attended with a very small risk to life. The prejudice against the use of caustics is in our profession very strong, partly because they have fallen for the most part into the hands of quacks, partly because we are not in the habit of employing them, and are in practice equally ignorant of their vices and their virtues." After speaking of the bone-setters, he concludes: "In the same way, many of our patients with cancer fall, through an apprehension of the knife, into the hands of cancer-quacks, and are treated successfully, at least as successfully as we could treat them, by means of caustics. As we have endeavored to meet and defeat the bone-setters, so must we meet and defeat the cancer-quack; not by ridiculing his methods and refusing to credit the account of his successes, but by making his methods our own, and by employing them with a far better knowledge of disease than he is ever likely to attain to."

To this might be added that if a specific germ should be proven as the cause of this worst of diseases, then we can look for some simple germicide that will serve to render all present treatment useless and antiquated.

What could be more earnestly desired by surgeons of the present day?

A CASE OF ACCIDENTAL DROWNING.[1]

BY FREDERICK WINSOR, M.D., WINCHESTER, MASS.

GENTLEMEN OF THE MASSACHUSETTS MEDICO-LEGAL SOCIETY: — An address from the retiring president would doubtless be received kindly and patiently by the members before me; but the present incumbent has nothing to offer which is worthy to be called an address, and he is unwilling to waste your time with perfunctory speech. There are, however, a

[1] Read before the Massachusetts Medico-Legal Society, June, 1888.

few points to which he will venture to call your attention.

Our attempt to obtain a change in the law regulating expert testimony, by which it would gain in dignity and in value and greatly advance the purposes of justice, has failed — failed for the present only. The reform we seek must come, for it is in the interest of good sense and truth. What is so plain to the medical profession must gradually become evident to the majority of the bar and the bench, who now fail to see that it would help them, as well as us and the whole community. Let us bide our time, and by and by press the reform again, leaving the initiative to those members of the bar whose eyes have been opened.

Our Society has reached a stage of development when it needs, not so much fresh rules and maxims, as the faithful use and practice of those with which it has supplied itself. "The Law of Medical Examiners" has been sufficiently elucidated and expounded. When to make a view, and when to refuse; when to ask permission to make an autopsy; how to conduct and record the autopsy, with the adjuncts, it may be, of chemical and microscopical expert investigation; to keep to *our* function, and leave to the court and the lawyer what belongs to them, — the *theory* of all these matters has been made plain to each of us, and admirable illustrations of its application to practice have been furnished in papers with which our publications are enriched. Familiarity with such applications is, perhaps, what is most needed by the individual examiner; but what the Society most needs is the readiness and habit on the part of every member to prepare for report and to present at our meetings such of his cases as are unusual and instructive.

It is obvious that such a habit would conduce greatly to accuracy and thoroughness in making views and autopsies; while it is almost essential to the well-being of this Society, which languishes to-day for want of just such nourishment.

Those of us whose cases are few — too few to make us as familiar as we feel that the medical-examiner should be with the application of the instructions we have received — are no doubt deterred from reporting cases by the suspicion that what is to us novel or puzzling, may be to our more experienced and accomplished associates an old or a trifling and tedious matter. But this risk must be encountered by every one who cares to learn; and it is in the hope of drawing some better instruction from others that I submit to this meeting the following report of a case: —

The following case was one in which the decision of the medical-examiner was questioned, and an inquest was held:

June 23, 1884, at 7.45 P.M., I was summoned to Woburn, to view the body of a woman which had been found, three and a half hours earlier, floating in shallow water on the shore of Horn Pond, near a place known as the "Swimming-Hole," distant about a quarter of a mile from any road or dwelling.

The officers who took the body from the water reported that they found it floating face down in water about two feet deep; the back, hips, and back of one leg were above water, the head and arms were more deeply submerged, the fore arms and hands resting on the bottom (which was of sand and pebbles). Close by, six or eight feet from the water's edge, her clothing lay in an orderly pile. The ground in the neighborhood was not trampled, and showed no signs of any struggle.

I found at the undertaker's room the body of a middle-aged, well-nourished woman, naked, cold and rigid. The face was not livid, and but little swollen. The eyelids were closed, the face placid. The teeth were clenched, and the tip of the tongue was between them, but not bleeding and not protruded between the lips. About the mouth and nostrils was a little blood, which came from cuts and scratches near by, — one on the right cheek, near the nose; several on the lower lip; all in the same general horizontal line, and all superficial. The tragus of the right ear was also slightly cut or scratched, and smeared a little with blood from the scratch. There was no froth at the mouth or nostrils. The right hand was clenched; the left partly so. There was cutis anserina on the front of the body. On the back of the trunk a few spots of hypostatic discoloration were seen. There was no other bruise, wound, or mark on the body.

Palpation showed that the womb was not enlarged; percussion, that the thorax was normally resonant.

From the husband I learned that he last saw the woman alive at 5.50 A.M., of the same day, when he left home for his work, she having cheerfully got him a good breakfast and seeming well. Returning at noon, he did not find her, and was told by his children (her step-children) that they had not seen her since they rose (about 7 A.M.). He and they supposed that she had gone — as she sometimes went — to visit her relatives half a mile away and nearer the pond. By the children I was told that she had several times said "she should like to have a bathe in Horn Pond." None of her immediate neighbors saw her leave home that morning.

She was well known in Woburn, and generally understood to be of inferior mind, and to have no delicacy of feeling and small sense of decency. I talked with her brother, as well as with her husband, and could not learn that she had ever been subject to "fits," or had spoken of suicide. I did learn, however, that she had "queer times," when she was very absent-minded, red in the face, and not well aware of what was going on, — although she attended fairly to her housework at such times.

The other relations were Protestants and of New England descent. Her husband was Irish Catholic, and had been forced into the marriage by her swearing him to be the father of her illegitimate child; and they did not live very harmoniously, though there were no stories of violence between them.

Her brothers gave me to understand that they suspected foul play on the part of the husband and his Catholic friends. They propounded vague theories as to her being abducted by night, and drowned, or dropped into the pond after being poisoned.

I saw no reason for asking an autopsy, nor did they call for it; and I reported the case to the District Judge as one of "accidental drowning."

The theory which seemed to me consistent with the observed facts, and with the woman's character and history, is that she was subject to epilepsy of the slighter form; that, under the influence of an approaching attack, she started to bathe in the pond; that by the time she had undressed and entered the water, she became dizzy and unconscious, fell face downward, and smothered with little struggle, perhaps with spasm of

the glottis. The very slight scratches on the face and ear might well have been abrasions made by the pebbles on the bottom.

The suspicions of her relations grew with dwelling on the strange death, and they employed two resident physicians to make an autopsy within forty-eight hours. I was not notified of the autopsy, but heard at the inquest their testimony, which was not from notes, but from memory. It was negative, — so far as regards the finding of any appearances to account for the death, — with the exception of an effusion or infiltration of bloody serum (rather insignificant in extent and vaguely described) into the substance of the upper half of the right pectoralis major muscle. There was no ecchymosis or other mark on the overlying integument; no injury of the clavicle or ribs. They found no evidence of poison. Their opinion was that death was not by drowning, because they found very little fluid in the stomach or in the plural cavities or air-passages; no froth, or but little, in the air-passages; and no special congestion or lividity of the head, neck, and upper chest. They believed that the woman was roughly used and killed before she was put into the water, and that some one probably knelt on her chest.

The finding of the Court was, "Death from cause unknown."

Nothing that transpired at the inquest has changed my opinion as to the cause of death in this case, but I submit it here to your criticism.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.

MEASUREMENTS OF LONG BONES AND ESTIMATION OF THE HEIGHT.[1]

Dr. Étienne Rollet has written a paper on this subject which appears to have attracted a good deal of attention. It is based on measurements of the height of fifty male and fifty female bodies, and then of the length of the three long bones of the arms and legs of both sides. Such observations are very valuable, both from a scientific and a medico-legal standpoint. We shall have to criticize some of the deductions, but we would praise warmly the collecting of the statistics. In the first place the author compares the two sides with very interesting results, though we must remark that the series are far from large enough to be satisfactory, and that we should have liked to have had, not only the average difference between corresponding bones, but greater details as to the number of bones that varied considerably from the mean. The thigh bones are rarely equal, and either side may be the longer. The average difference, however, is slight; namely three millimetres, but in one case it reaches one centimetre. There seems to be little or no difference in this respect between the sexes. The tibiæ are often equal in the male; but they may be uneven, and the inequality is on an average two millimetres in favor of the right. It may reach five millimetres. Only four times was the left tibia a little the longer, and in these cases the left femur was the longer also. In women the inequality is more often in favor of the left, and sometimes in these cases the right femur was the longer. We omit the fibula as of little importance, as it is no true factor in the height of the individual. Twice among the men the lower limbs, as shown by the combined length of the femur and tibia, were equal. The average of the inequality was three or four millimetres, though it might reach one and a half centimetres. One side was about as likely as the other to be the longer. In the women the conditions were essentially the same. Sometimes the longer femur had the shorter tibia below it. Sometimes both bones of one side were longer than their respective fellows.

The results of observations on the superior extremity are more constant. The right humerus was almost always the longer. The two were equal only twice in each sex. The left was the longer only once among the men and twice among the women. The average excess of the right was five millimetres, and it some times reached even twelve and eighteen millimetres. The same general statement applies to the radius and ulna; the right is almost always the longer, and the average excess is three millimetres. Considering the arm and forearm as one, it appeared that the two sides were never equal in man, and only once in woman. Only once in man, and twice in women, was the left arm the longer. The average excess of the right was from seven to eight millimetres.

Statistics are wanting to show the age at which asymmetry begins. The author made a few measurements which showed that at birth the length of corresponding bones was equal, but he found a difference between the radii in a child of four months, and in another of twelve months. In a child of six, all the bones in question, except the fibulæ, were unequal. The observations, however, are far too few.

M. Rollet then gives the proportions of the different bones to the height, in both men and women, dividing the individuals into four groups according to height. If we assume that the number of subjects was divided as equally as possible (which is unlikely), each group would consist of only twelve or thirteen individuals, which is insufficient. We pass on to the third part of his work, that in which he gives five methods of estimating the height of an individual from the long bones or from one of them. The first method to which he gives the preference is by means of the tables which he has made, in which both males and females are divided into four groups according to height, and the average lengths of the long bones of each group are given. All that is necessary, knowing the length of a bone, is to find the group in which the length of the corresponding bone most nearly approaches it, to take the average height of that group, and, by a simple application of the rule of three, to find the height that was wanting. Thus the length of a given femur being L, the height of its late owner being X, the nearest average femur being A, and the height of that group being H, we have $X = \frac{H \times L}{A}$.

The second method is essentially similar. He gives tables of heights of individvals, two centimetres apart, fifteen of men and seventeen of women, with the length (we presume the average length, as found in the author's observations) of the bones opposite. Knowing then the length of a bone, you look for it in tables. If you find it precisely, you take the height in the same line. If it is not found precisely, you again have recourse to the rule of three. The third method appears to be to compare the length of the known bone with that of the mean femur, and know-

[1] Archives de l'Anthropologie Criminelle et des Science Pénales, to me iv, Mars, 1889.

ing the mean height, to go through the same process again. He gives a table of the mean length of the bones for both men and women. The fourth is still by the rule of three, and is done by tables showing the proportions of the different bones to the height, the latter being one hundred. The fifth method is a purely arbitrary one, which is, at all events, much less complicated than Bedoe's, which we described in the Report a year ago. It consists simply in multiplying the length of the known bone by the corresponding figures, as shown in the following table.

	Femur.	Tibia.	Fibula.	Humerus.	Radius.	Ulna.
Male,	3.66	4.53	4.58	5.06	6.86	6.41
Female,	3.71	4.61	4.66	5.22	7.16	6.66

This paper has attracted a certain amount of attention in France, but the part devoted to the estimation of the height is subject to a good deal of criticism. Rollet's first method is, we think with him, the best; but it should rest on tables composed from very many more measurements than his, and from which very old individuals should be excluded. But both in medico-legal practice and in ethnological investigations, the system is vitiated by the assumption that the murdered man, or the prehistoric race, had the honor of possessing the proportions of the Frenchman of to-day.

THE ARCHITECTURE OF THE FOOT.[2]

Prof. W. Rasumowsky has studied the internal structure of the bones of the foot in a somewhat original manner. His method strikes us as an excellent one. It consists in freezing the whole foot, and in cutting with a saw slices two or three millimetres in thickness. These are first cleaned by a stream of water and then put for several days into strong alcohol, after which they are made transparent by turpentine, or better still, oil of cloves. How they are mounted, if at all, is not stated: but they are examined by direct light, under oil of cloves. A lens may be used with advantage. The soft parts are rendered so transparent that one tissue is hardly to be distinguished from another, but the structure of the spongiosa is said to show many details not seen in sections not treated in this way. We own that we are sceptical that they are better than very thin sections properly cleaned, but what pleases us in the method is that it allows the foot to be studied as a whole.

One of the features which the illustrations at once make evident is that each bone cannot be considered as a whole in itself, but that some at least of its lamellæ belong to systems extending beyond its confines. Another is that in some cases the fibres of interosseous ligaments appear to be conecting links between systems of plates in separate bones. The illustrations, unfortunately, are from drawings, and do not therefore carry the conviction which follows photography, and which would be particularly welcome in this question of the possibility of direct continuity between fibrous tissue and bony plates.

It would be unprofitable to give the results of these studies in detail. There is the well-known system of struts and ties. Antero-posterior arches, with one pier in the heel-bone, diverge through the five metatarsal bones. The lines of these arches are, however, not continuous, but are interrupted at the summit, those of the three inner toes in the astragalus and those of the two outer in the os-calcis. Frontal sections show transverse arches in the front part of the tarsus. These are said to be connnected by a system of ties, partly of bony plates, partly of ligaments; and in this connection we must repeat that we wish the illustrations were less diagrammatic. A frontal section through the astragalus and os-calcis shows a series of plates in the main vertical, but with a tendency to incline inward in their course through the lower bone. The author points out a resemblance between a frontal section of the sustentaculum tali and one of the neck of the thigh bone.

A POINT IN THE ANATOMY OF THE FIRST CUNEIFORM BONE.[3]

Messrs. Hartmann and Mordret have made a curious discovery concerning the first cuneiform bone of the foot, which is situated between the scaphoid and the metatarsal bone of the great toe, to wit, that it shows signs in many cases of a tendency to divide into two. They state that, in the majority of cases, there is a tendency to a contraction of the breadth at the middle of the anterior surface; and we must own that we are not clear that, so far, they have discovered anything that was not known before. Gray describes this surface as reniform, which implies a constriction on one side.

Their next step, however, brings us to something very new, and which one is surprised should have been overloooked. It is that in twenty per cent. of the cases the anterior surface is distinctly divided into two by a minute furrow, as if drawn by a needle, in the middle, and growing larger at its ends. They frequently found a delicate band of areolar tissue attached to it. When this exists there is a corresponding minute ridge on the back of the metatarsal bone, far too small to be of any surgical importance. In two per cent. of the cases the cuneiform was completely split into two bones, one above the other, presenting opposed articular surfaces except at the outer anterior angle, where there is an interosseous ligament. When the separation is complete, the anterior surface of the scaphoid shows four instead of three articular facets. These observations were made on three hundred feet. The authors find that the peculiarities were symmetrical. The division of this bone into two is already known as a rare anomaly. Le Dentu has thought that it had two centres of ossification, which unite at four years. Our authors appear to have examined few children's feet, and have never found two centres, though once the centre showed signs of a constriction near its middle. The scientific significance of the tendency to divide may be of considerable importance.

EXPERIMENTS IN CRANIO-CEREBRAL TOPOGRAPHY.[4]

Messrs. William Anderson and George Henry Makins read a paper before the Anatomical Society of Great Britain and Ireland, describing a very interesting study of the variations of the course and position of some of the chief fissures. Now that cerebral surgery has a recognized standing, the importance of an accurate placing of the main features of the motor region is self evident. The method pursued by these gentlemen is an ingenious one. Their observations were divided into three groups. The plan may be described in their own words:

"A preliminary series of examinations were con-

[3] Bull. de la Société Anatomique de Paris, 1889, fasc. iv.
[4] Journal of Anatomy and Physiology, vol. xxiii, April, 1889.

ducted with a view to gain certain approximate data as to the relations of the three principal fissures to the cranial walls. Upon the indications so obtained were founded a second and larger set of investigations, mainly guided by experimental punctures made at certain test points upon the scalp; and lastly, a number of adult crania of different types, but free from abnormalities of form or development, were submitted to measurement with a view to determine the range of variation of the principal sutures, eminences, and ridges in their relation to each other and to certain standard lines drawn upon the surface of the skull."

In the first series but one side of the vault of the skull was removed, the dura opened, and the course of the Fissures of Sylvius, of Rolando, and the external parieto-occipital, determined, and then marked with colored mucilage on the outside of the dura, which had been accurately replaced. The separated portion of the calvaria was then replaced, and the head turned so that the mucilage on the dura left its mark on the inside of the skull. The piece of bone was then removed, and holes drilled through it along the lines of the fissures. The relations of these lines to the sutures and eminences were then carefully noted. From these observations a brain-plan was drawn upon a skull of average dimensions. Provisional points were selected for certain points in the fissures; and three standard lines were drawn on the scalp, for their localization.

The second series consisted of experiments made from these lines which were drawn on the scalp. Holes were then drilled through certain points in them, and pins thrust through. It was then easy to expose the brain, and mark the relation of the punctures to the fissures.

The third series consisted of measurement of certain lines on thirty skulls, in order to ascertain the value of the sutures and eminences as guides to regions of the brain. We must omit the details of the bony measurements. Suffice it to say, that most of the points varied considerably. Three, however, are both relatively stable and easily recognized during life, namely, the glabella, the external angular process of the frontal bone, and the external occipital protuberance. It was found that the relations of the convolutions to the surface of the skull and to each other varied "within rather wide limits." The course of the fissures (apart from their relations) was found to be very uncertain. A series of tracings of the Fissures of Rolando shows some surprising meanderings.

We must now define the arbitrary lines which were chosen for standards. They are (1) the sagittal line, from the glabella, at the level of the highest point of the orbital arches, to the external occipital protuberance; (2) the frontal line (an unfortunate name), from the mid-point of the sagittal line to the depression immediately in front of the tragus of the ear; and (3) the squamosal line, from the most prominent point of the external angular process, at the level of the superior border of the orbit, to the junction of the middle and lower thirds of the frontal line, and prolonged an inch and a half beyond it. The upper end of the Fissure of Rolando was always found between the mid-sagittal point, that is the point in the middle of the line, and one three-quarters of an inch behind it. The distance from the mid-sagittal point bore, however, no constant relation to the length of that line. The lower end was found in the squamosal line, between the point where it cuts the frontal line and a point three-quarters of an inch before it. As already stated, the course of the fissure between these points was often remarkably irregular.

As to the Fissure of Sylvius, its point of starting is necessarily rather a vague spot. It is in the squamosal line, between one and one-eighth inches and an inch and a half behind the external angular process. The bifurcation is in the same line, between an inch and a half and two inches from the angular process. The main branch of the fissure follows the squamosal line closely; but it turns up at its end, which is near the parietal eminence. The authors state, however, that a circle an inch in diameter would fail to enclose all its variations.

The external parieto-occipital fissure is on an average seven-twelfths of the distance from the mid-sagittal point to the occipital protuberance, in other words, near the apex of the lambdoidal suture. Judging from the diagram, there is less variation in its situation than might have been expected.

THE ANATOMY OF THE PROSTATE.[5]

Mr. Joseph Griffiths, rightly thinking that our knowledge of the prostate is unsatisfactory, has studied it anew. He finds that the third lobe is not always present, but that when it occurs it is one of the original parts of the prostate, or at least one that appears early, and is not merely an extension of the other two. We referred some years ago in these reports to a paper by Mr. Harrison, of Liverpool, on the "Prostate Muscle," in which he maintained that the organ is essentially a muscular one. Mr. Griffiths, on the contrary, believes that it is essentially glandular. The following are his chief conclusions:

"(1) *The third or median* lobe exists, in many instances, as a well-defined portion of the gland at puberty and adult life, that is, the period before enlargement of the prostate occurs; but in other instances, it is very small or entirely absent.

"(2) This part, or lobe, possesses ducts of its own, which open upon the parts of the hinder wall of the prostatic urethra, which extends from the vesical orifice to the *verumontanum*.

"(3) This part, or lobe, also develops separately from the part of the urethra just mentioned, in the same way as the lateral lobes do from the part of the urethra on each side of the *verumontanum*, and it is not the result of an extension backwards of gland tissue from the lateral lobes into the interval between the vasa deferentia and the neck of the bladder.

"(4) The whole gland is peculiar in this particular, that the 'ducts' are short, and form mere channels in the stroma, being destitute of any special coats, except a layer of epithelium lining them; and that the muscle tissue of the prostate is so arranged around the termination of the 'gland tubules' which form the secreting parts, that the muscle, when it contracts, is able to act as an efficient expulsor along the whole course of the tubules.

"(5) This arrangement of the muscle in the prostate is developed in relation to the function of the gland; and thus it is that the secretion accumulated in the tubules can be completely expelled into the urethra at once, or at least in a short time.

"(6) The muscle-element of the prostate is derived

[5] Journal of Anatomy and Physiology, vol. XXIII, April, 1889.

from the outer, circular, non-striped muscle-coat of the prostatic urethra, this coat being continuous with the circular-coat of the bladder; therefore the muscle-element of the prostate is only indirectly continuous with that of the circular-coat of the bladder.

"(7) The *utriculus masculinus* is not, properly speaking, embedded in the prostate. It forms a distinct structure separate from the prostate; and as the growth of the prostate greatly exceeds that of the *utriculus masculinus*, the latter is in time covered in, and appears as if imbedded in the former."

Clinical Department.

A CASE IN WHICH THE NIGHT-CRIES OF HIP DISEASE WERE STOPPED BY FLEXING THE LEG.

BY JOEL E. GOLDTHWAIT,
Formerly Interne at the Boston Children's Hospital.

B. D., a healthy looking child, six years old, was admitted to the Children's Hospital, May 25th, and entered the service of Dr. E. H. Bradford, through whose kindness I am permitted to report the case.

She has had hip disease for the past nine months, and has been under treatment for the last six, during which time she has worn a hip splint, a high sole on the well foot, and has walked with crutches.

The first three months of treatment she did very well, but after that she began to cry out in her sleep, at first only once or twice, and then as many as fifteen or twenty times during the night. There were no other acute symptoms; no signs of an abscess; no pain; no apparent deformity, either flexion, abduction or adduction; and the motion in the joint was by no means entirely restricted.

Because of the severe "night-cries" she entered the hospital. For the first two days she was kept in bed on a "Bradford frame," with the leg fixed by means of sand bags and a weight of four pounds for extension. Each night she cried out sharply many times. She was then given ten grains of the salicylate of soda, four times a day, as suggested by Dr. Lovett.[1]

In the majority of cases this treatment has stopped the cries in a day or two, but in this case the soda salt was continued for about two weeks without any diminution in the night-crying. (During this time the extension weight had been doubled, without giving relief.)

On June 11th, by way of experiment, the salicylate of soda was omitted, and the leg was flexed at an angle of about thirty degrees with the bed, and the weight raised to pull in the same direction. That night she cried out once, and upon the six following nights she slept soundly all night.

On the night of the 18th of June the leg was put down flat upon the bed, and she cried out once. This was repeated the following night with the same results. Again the leg was raised, and up to the time of discharge, with the leg held in this position, there were no more night-cries.

During the greater part of her stay at the hospital she was up and about the ward during the day, and the leg was flexed only at night. She is to carry out this same treatment at home.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE. SECTION ON ORTHOPEDIC SURGERY.

STATED MEETING, March 15, 1889. A. B. JUDSON, M.D., Chairman.

CICATRICIAL CONTRACTION OF FINGERS.

Dr. A. M. PHELPS presented a patient on whom he had operated four weeks ago for restoration of motion to the fingers, which had been flexed in the palm by a cicatrix in the wrist of eight years' standing. He had freed each tendon from the cicatricial tissue, and had secured healing by blood-clot, with the hope that new sheaths would be formed in the clot. The wound was dressed antiseptically, and the first dressing was changed at the end of three weeks. The prospect of recovery of motion was good.

DR. R. H. SAYRE said that Paget had long ago recognized the organization of blood-clot after subcutaneous tenotomy. The case presented by Dr. Phelps shows that advantage can be taken of it after open incision under antisepsis.

HYSTERICAL EQUINO-VARUS.

Dr. N. M. SHAFFER presented a patient, a girl of twelve years, who had been affected for ten weeks with hysterical equino-varus and rhythmical movement of the left foot. The talipes was reducible manually, but the motions were persistent. There was inability to walk, the result of the disability of the quadriceps extensor group. Before coming under Dr. Shaffer's observation, plaster of Paris had been applied to the limb for several weeks, but without benefit.

DR. A. B. JUDSON thought that choreic elements were seen when the patient attempted to walk. He recalled a case of rhythmical myoclonus reported by Dr. Peckham in the Archives of Medicine in 1883, in which the patient had been subjected to a great variety of treatment, and recovered finally after the hypodermic use of atropine.

DR. S. KETCH suggested treatment by hypnotism.

DR. R. H. SAYRE thought that the case illustrated the fact that abnormal muscular contraction can produce degrees of deformity as marked as those caused by bony distortion.

DR. L. W. HUBBARD thought the case allied to chorea, being the result of nerve irritation or exhaustion. He suggested absolute rest or recumbency for a long period, with efforts to improve the nutrition.

DR. A. S. HUNTER had treated with success a case of hysterical hip by the administration of ignatia amara. The use of this drug in a number of cases of this kind has led him to value it highly when the disturbance was limited to groups of muscles only; but he thought it was of little value in the treatment of general choreic conditions.

DR. V. P. GIBNEY had had a favorable effect in a case of rotary spasm of the neck, from the fluid extract of gelsemium, given in five minim doses, and pushed almost to toxic effects.

DR. H. W. BERG said that the contractions in the case shown could not be due to nerve lesion because it yielded too readily to manual replacement. Where there is irritation of motor nerves, as in spastic paralysis, it is extremely difficult to reduce the limb to a proper position. He suggested the ordinary treatment of

chorea with electricity, to make an impression on the mind rather than on the nerves.

THE MANAGEMENT OF HIP-JOINT DISEASE.

The paper of the evening was read by Dr. Phelps, entitled

THE MANAGEMENT OF HIP-JOINT DISEASE FROM AN ANATOMICAL BASIS.

In regard to the pathology of this disease, Dr. Phelps believes that it is a local tuberculous affection due to accidental inoculation and not to a constitutional or strumous condition. Following Volkmann, Albert, and König, he believes that the inflammation at first simple, becomes tubercular by inoculation, and then purulent. The irritation of the peripheral extremities of the nerves in or about the joint produces muscular spasm, which in turn distorts the joint by trauma aided by the bacilli of tuberculosis.

In regard to treatment, he relies on mechanical treatment, believing that if we immobilize a joint and remove the intra articular pressure, nature will take care of the tuberculous material. His experiments on dogs had convinced him that immobilization of healthy joints does not produce anchylosis. Encouraging motion in an inflamed joint is a violation of the surgical law that an inflamed part requires rest.

He believes that the muscular spasm, which is a most serious element of destruction, should be overcome by extension, and that while extension is necessary to secure immobilization, it is not sufficient by itself. He therefore resorts to a combination of extension and fixation; the extension to be in a line corresponding to the axis of the neck of the femur.

Treatment as a rule should be begun in bed, extension being made in two directions, that is, toward the footboard and laterally, the body and well leg being fixed to a long splint extending to the axilla. If the deformity does not yield to extension properly applied, the tissues at fault should be divided subcutaneously or by open incision. Abscesses are to be incised through their entire length, and thoroughly scooped out and washed, strict antiseptic precautions being observed.

Distension of the capsule should be relieved by aspiration or incision; then traction will not produce pain.

He exhibited a patient in a portable bed, which is an ingenious substitute for the wire cuirass, made with a board cut in an outline of the body, and plaster of Paris. The child is laid on the board and then the whole enveloped with plaster of Paris bandages from the foot to the axilla. The plaster is then cut away in front, the interior comfortably padded, and the patient held in place by lacings or bandages. Extension and fixation in bed are to be continued until the active symptoms and the deformity have entirely disappeared and the spasm of the muscles is no longer present. Adults are then given crutches and a portable splint which has a perineal crutch, extension by adhesive plaster, an abduction bar, and an upper (thoracic) ring to prevent flexion and extension at the hip. Children, after treatment in bed, are to have the portable bed, and then the portable splint, with or without the high shoe and crutches.

Dr. J. Ridlon was pleased to hear the author of the paper take the ground that hip cases should be cured without deformity. He recalled a case of a patient in which the muscular spasms had been relieved by pinching the muscle. The child was very thin, and it was found that when the adductors were separated from the other muscles, and the belly of the muscle was pinched without any attempt at fixation, there was as much relief as could have been afforded by lateral traction.

Dr. Shaffer said that the paper had suggested to him the importance of separating, in our minds, the disease from the deformity. It is a question how far we are justified in meddling with the deformity, which is simply an expression, or so to speak, a symptom of the disease. In his experience, attempts at speedy reduction of the deformity had been followed by disastrous results. Nature gives a very positive indication in the acquired position of the thigh, that in which the immobilization of Nature reaches its maximum, and the diseased parts receive the greatest relief from reflex muscular spasms. If we forcibly interfere with this effort on the part of Nature, we inflict a distinct traumatism.

On the threshold of treatment, the important question is, not whether traction is to be made in the line of the shaft or the neck, but how to secure an artificial immobilization in the position nature assumes as the one that affords the most protection to the inflamed parts. He believed that if the joint was protected from traumatism, in other words, if traumatic contact of the inflamed joint surfaces is removed,— and this can readily be done by the use of portative apparatus without entailing immobilization of the entire body from the head down,— the joint is placed in the best-known local condition.

The portative traction treatment is compatible with fresh air, sunlight, and moderate exercise, which are the best means of combating the tubercular disease, and the tubercular diathesis. More lives have been saved, and better results have been thus secured, than by any other method which has been thoroughly tested.

Dr. R. H. Sayre agreed with Dr. Shaffer as to the importance of maintaining the general health, and the inadvisability of general immobilization of the body, if the diseased joint could be controlled without it. He thought that complete immobilization of the hip-joint in young children was very difficult to secure; and that the movement that stopped short of producing muscular spasm and pain, was not harmful. For poor children particularly, he thought the portable bed was an admirable contrivance.

The relief obtained in some cases by pinching the muscle could be explained on the supposition that it stopped the reflex action of the muscle. It is known that firm constriction of the belly of a muscle will, in certain cases, abolish spasm.

Dr. Charles L. Scudder, of Boston, advocated a more frequent resort to the results of experiment on the cadaver. He recalled Dr. Bradford's experiments made in 1880, in which it was found that in an adult a force of one hundred pounds was not sufficent to separate the head of the femur from the socket; while in the shallow and not yet completely ossified acetabulum of a young child, a moderate force caused separation, and still less force was required in the fœtus. Dr. Scudder believed that in hip-disease of children, a tractive force of from three to five pounds would separate the joint surfaces, as was illustrated at the Children's Hospital, in Boston, in the case of a young boy who had hip disease and

night cries. The joint cavity was opened and a small quantity of pus evacuated. While the boy was under ether, it was found that traction made with the hand separated the joint surfaces to such an extent that the finger could be placed between the head and the acetabulum.

DR. HUBBARD thought that no one at the present time held the opinion that anchylosis is caused by immobilizing the joint affected with chronic inflammation. He had found it difficult to get anchylosis in cases where it was desirable, as in disease of the knee. The first object is to give rest to the joint, which is best done by traction; not to separate the surfaces, but to overcome articular pressure which leads to muscular spasm. He believed the long hip splint gave sufficient immobilization for all practical purposes. It is more easily managed than the portable bed of Dr. Phelps, which from neglect would be likely to cause excoriations. As the disease seems to be a struggle between the tubercle bacilli and the vitality of the organism, he thought it especially important to place the system in the best possible condition to resist the attack. He had rarely seen constitutional disturbance from abscesses which had been let alone, although in exceptional cases acute and painful conditions are certainly greatly relieved by surgical interference.

DR. JUDSON commended the title of the paper. It was an admission that hip disease is not to be cured by treatment, but so managed that the almost inevitable recovery by natural processes should be with the minimum of disability and deformity. He thought that more emphasis should be placed on the importance of protecting the joint from the traumatisms of standing and walking, as is done by the use of Hutchison's extra long crutches and high sole on the well foot. But in every case there are long periods of exemption from pain, when this simple apparatus will be discarded. The ischiatic or perineal crutch of the hip splint, however, cannot be willfully discarded; and when it is seen that the rack and pinion not only furnish traction but also a convenient means of adjusting the length of the upright, the hip splint appears to come very near perfection as an instrument for the management of hip disease. He had never recognized either the trauma said to be caused by reflex muscular contraction or the alleged mechanical counter-action of the muscles by traction. He believed, and had always held, that the hip splint mitigates reflex muscular contraction by allaying the inflammation which gives rise to it. This it does by arrest of motion and prevention of pressure; motion being arrested by traction brought about by the use of the key, and pressure being averted by the perineal or ischiatic crutch, which makes the limb a pendent member. As the inflammation is resolved the reflex muscular contraction ceases.

The last annual report of one of our orthopedic institutions contains a table, from which it appears that there have been under treatment 371 cases of disease in the hip; 6 in the shoulder; 85 in the knee; 3 in the elbow; 27 in the ankle; and 5 in the wrist; an aggregate of 483 in the lower, and 14 in the upper extremity. Shall we draw the inference that the incipient osteitic focus is found only or chiefly in the cancellous tissue of the lower extremity, or that a focus in the upper extremity more readily undergoes resolution by reason of its comparative exemption from violence? If the latter view is correct, it follows that the limb is to be made a pendent member by the persistent use of the axillary or ischiatic crutch at the earliest recognition of the disease. In some cases, an early diagnosis may be facilitated by the following simple method:

Let the patient sit on a table with the legs hanging and the knees separated: in this position, swinging the leg laterally is possible only with rotation of the femur; and if one leg oscillates in a less arc than the other, it induces or confirms a suspicion of the integrity of the joint.

He did not believe in treating abscesses and sinuses except indirectly through general and local management of the bone disease in which they originate.

Dr. Gibney was in favor of securing absolute immobilization, but sometimes he would rather have less perfect immobilization, if by so doing he could secure a change of air and climate, with the consequent improvement in the general nutrition.

Ordinary hip disease is managed satisfactorily by the portable traction splint, with or without the rack and pinion; and he had been agreeably surprised with the facility with which these patients ran around in the tenement houses. They come to his clinic only every three or four weeks for adjustment of the apparatus; and during these intervals engage in the most active sports: they certainly do not lie in bed in dark rooms and die of pyæmia. It is unsafe to put these children in an appliance like a cuirass or the portable bed, unless one is certain of being able to attend to them at short intervals. It had been his lot to see cases in which he had been unable at times to obtain proper co-operation on the part of the patient's family. He had often seen abscesses burrowing up to the spinal column and down to the knee; and such cases seemed to baffle even attempts at surgical interference. We must be guided a good deal by circumstances, and if we can protect the hips from trauma and give the patient the benefit of out-door exercise, abscesses will generally be insignificant.

He believed in correcting the deformity speedily, if necessary, by dividing tendons and bone under an anæsthetic; for, by so doing, we save much time and lose nothing.

In regard to aspirating the joint over-distended with fluid, it was almost impossible to diagnosticate an over-distended hip-joint. The position of the limb does not depend on the quantity of fluid in the joint, but is due to reflex spasm, and the efforts made by the child and nature to secure fixation.

DR. J. H. GIRDNER described an experiment on the cadaver in which great force was applied without separating the surfaces of the hip-joint. He also cited a case in which it had been necessary to keep the hand applied to the face for nine weeks in the course of a plastic operation on the nose. At the end of this time there was no limitation in the motions of the elbow and wrist.

DR. KETCH believed that hip disease is so often characterized by exacerbations that all attempts at a division into stages are of no practical value. He thought that the hip splint could be often of use for the reduction of deformities, even in those periods when the patient is confined to his bed. In general, he believed it was a great mistake to make use of any apparatus which can be entirely left to the care of the patient or family for long periods.

The explanation of the relief of pain by compression of muscles was to be found in an involuntary action on the part of the patient, which secures fixation and traction at the same time.

DR. BERG, speaking from the standpoint of the general practitioner, who frequently saw children in the very beginning of hip disease, related the histories of three cases which had presented the symptoms of early hip-joint disease and yet recovered perfectly after a rest in bed for a few weeks. He now insisted on all patients remaining in bed for several weeks before commencing any other treatment.

DR. PHELPS, in closing the discussion, said that many cases in tenement houses, whether treated by the long traction splint or by the portable bed, are deplorably neglected; but this does not argue against the use of either apparatus: it simply illustrated one of the difficulties with which all practitioners have to contend. He valued the portable bed because he desired immobilization of the affected joint, and this could not be obtained with splints having joints in them, and not including the trunk. He could relieve his patients better in bed during the period of deformity, and so adopted this method of treatment. He had seen patients in England who had been in bed for several years, and were still in excellent health. He did not, however, advocate prolonged bed treatment. Believing that the cases in question are inoculations of the bacillus tuberculosis on a previously inflamed surface, and not instances of constitutional tuberculosis, he explained the frequency of tubercular joint diseases in the lower extremity, by the statement that the joints of the lower extremities being more subjected to traumatic inflammation, furnish good ground in which the bacillus of tuberculosis could more readily reproduce itself.

He had presented his honest convictions, and hoped to report his cases later in such a way that others could disprove his statements, or he could substantiate his views.

ANNUAL MEETING OF THE ESSEX NORTH DISTRICT MEDICAL SOCIETY.

E. P. HURD, M.D., CORRESPONDING SECRETARY.

THE Essex North District Medical Society met at the Franklin House, Lawrence, Wednesday, May 4, 1889, DR. C. G. CARLTON, President, in the chair.

DR. W. J. SULLIVAN, of Lawrence, read a paper on the

DISEASES OF THE HEART,

in which, in the brief space of half an hour, he took a wide and comprehensive survey of this vast subject.

DR. KATE C. HURD, of Newburyport, read a paper entitled

INTERESTING CASES OBSERVED IN THE NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN DURING THE YEARS 1888 AND 1889.

Twenty-six years ago this hospital was founded by Dr. Marie E. Zakrzewska, who was then professor of Obstetrics in the Female Medical College of New York. During the first year there were forty-one obstetric cases in this hospital. While Dr. Ann Preston labored untiringly for the establishment of the Woman's Medical College of Pennsylvania, Drs. Zakrzewska and Elizabeth and Emily Blackwell felt the imperative need of a hospital for women and children, where women who were pursuing the study of medicine could have clinical advantages for widening their medical education, and where at the same time female patients might be treated by their own sex.

The present hospital building was finished and in use in 1872. Its situation is in Roxbury, on a hill surrounded by fields and uncultivated lands, facing the northeast, so that every room in the house has direct sunlight during some portion of the day. The wards have each from one to four beds. The hospital charges varying somewhat with the number of beds. One-half the wards are devoted to surgical cases, and the other half to medical patients. The maternity cases are cared for in an entirely separate building, especially arranged to allow thorough cleanliness and antisepsis. This cottage, however, is proving too small, and plans are already made for a new house large enough to accommodate the women who desire to enter before confinement. Over 150 internes have already broadened their medical education by a year of practical work in this institution.

There is a training-school of twenty nurses, whose course covers eighteen months in the various departments, and to have obtained the diploma means that they have proved very faithful and efficient in the care of the sick confided to their charge.

The Maternity Department proves of great value to patients, internes and nurses. During the past eleven months 112 women have been confined there. Of these, fourteen were cases absolutely requiring the use of forceps. In two of them high forceps were used, the os uteri having been previously dilated artificially. Five were premature births; three were breech presentations; two were cases of transverse presentation requiring version; and three patients had puerperal convulsions, one before, the others after the birth of the child. There was one case of puerperal mania: the patient died insane at the McLean asylum.

To the female interne belongs the entire work of delivery and the directions to the nurses as to the preparation and after care. She is required to be very accurate in the diagnosis of position and presentation; and if during delivery there be a tear of the perineum, this is immediately repaired with stitches. Three of the primiparæ for whom the use of high forceps were needed, were torn through the whole perineum and sphincter ani. These ruptures were so promptly and thoroughly attended to, with complete antiseptic precautions, that the result was perfect union with entire control of the sphincter.

All the latest details of antiseptic midwifery are strictly carried out, and not a case of puerperal fever has occurred in this hospital for over five years. There has been but one case of mammary abscess.

After confinement the patient is lifted carefully and taken to another ward, which she is to occupy. After each room is vacated it is fumigated, and washed with a disinfectant solution, and the utmost pains are taken to prevent septic infection. The patient is given liquid diet the first day, light diet the second, and on the third day, full diet. She is required to nurse her baby regularly every two hours during the day and three times at night. During the intervening time, the infant is kept in another room, so that the mother may not be worried by its cries. On the tenth day, the patient sits up in bed half an hour, if all is well. On the fourteenth day she gets out of bed, if there be no contra-indications, and sits in a chair for

half an hour, and is allowed to sit up still longer on the following days, till the twenty-first, when, if in good condition, she is discharged. The dressings are pads of cotton antiseptically prepared, covered with bichloride gauze. These are renewed as often as soiled. If the lochia are at all offensive, a vaginal douche is given several times a day of corrosive sublimate, 1: 5000. All patients have douches from the tenth to the twenty-first day. After the fourteenth day a vaginal examination is made. Any laceration of the cervix uteri is at once treated by the modern methods. It is remarkable how rapidly a gaping tear of the cervix will heal under the occasional application of a strong solution of silver nitrite or pure carbolic acid.

Incipient mammary abscesses which do not yield to bandaging, ice bags and belladonna, are treated with hot applications of ammonium chloride in water.

The essayist gave an account of several of the most interesting cases occurring at the Maternity the past year, and then spoke of the surgical work of the hospital, one hundred and one operations having been performed during the past year. There have been eighteen laparotomy cases during the past eleven months, with three deaths. Six were hysterectomies for the removal of large uterine fibro-myomata. Six large ovarian cysts were emptied and excised, all with complete recovery. Other laparotomies were for the cure of hæmatocele, pyosalpinx, perinephritic abscess, etc.

One immense papillomatous cyst was removed. It was adherent to the uterus, rectum, bladder and posterior abdominal wall, In its removal most of the body of the uterus was taken out with it. The patient recovered, and is now doing housework.

The following interesting case from the essayist's notes is worth quoting in full.

When called to see this patient (Mrs. D., aged twenty-four, a Dispensary patient), December 1, 1888, I found her in bed, suffering intensely from what seemed to be an attack of localized peritonitis in the left inguinal region. She had been flowing for more than a week. Strength, appetite, sleep were absent. I ordered hot vaginal douches, gave her morphine suppositories for the pain, and ordered poultices over the seat of pain. Ergot considerably lessened the hæmorrhage. Pain subsided; appetite returned; and for a few days she gained rapidly.

December 7th, five days after my first visit, I found her again in great pain, with some bulging on the left side just above Poupart's ligament, and intense pain on pressure there. She had no fever; her pulse was good. The uterine hæmorrhage returned; and again the hot douches, the opium, the salines, brought relief. On the fifteenth day she decided that she felt so well that she would stay in bed no longer. She went down a long flight of stairs to her kitchen. Almost immediately the pain returned and was so severe that she was obliged to be carried to her bed-room. This pain continued with great intensity all night. The flowing began again, was very abundant; and the next morning I noticed that the tumor in the left inguinal region was much larger than before. It was easily defined; irregular, and as large as a goose's egg, felt both by internal and external manipulation, and seeming like a dilated tube. The question arose, is this a tubal pregnancy or a hæmato-salpinx?

During the entire illness with the discharge from the uterus there had occasionally passed shreds of membrane, sometimes as large as a silver quarter.

From her history I found that she had menstruated irregularly during her entire gestation, seven years previously, and that a short time before her present sickness she had had amenorrhœa, lasting six weeks, with morning nausea, a slight cough, etc., owing, she thought, to a severe cold; and she took hot drinks, hot foot-baths, etc., until the hæmorrhage commenced, which continued during the three weeks in which she was under my care, with greater or less severity and violent pain in the left side.

After this, the pain and flowing nearly ceased, though the tumor gradually increased; and again, without permission, she went down stairs, and while there had three sinking spells, each lasting fifteen minutes. I felt that it was fully time for the physician of the month, Dr. Emma Call, to see the case with me; this was brought about on the following day, and the case being diagnosticated tubal pregnancy, sent her out to the hospital. For the first week after admission the pains continued with frequent exacerbations and rapid increase in the size of the tumor. December 28th, the pain was with difficulty controlled by opiates, and the tumor doubled in size. A consultation of the surgical staff was held, and it was decided to make an exploratory laparotomy, and, if possible, to remove the growth. After the usual careful preparations, as to perfect antisepsis, bowels, diet, and other details, the operation was begun. The abdominal cavity was opened by an incision four inches long, below the umbilicus. Immediately beneath the peritoneum could be seen the tense bluish membrane forming the cyst-wall, on the left side, extending nearly to the umbilicus. The peritoneum was so adherent to this that it was with difficulty separated from it. The sac was punctured, and drained of a thick dark-colored and bloody fluid. It was found to be a much dilated tube with exceedingly thin walls. This was seized with cyst forceps and drawn out of the cavity, the broad ligament ligated; and the cyst, tube, and ovary of the left side were removed. The abdominal cavity was washed with boiled water, a glass drainage-tube inserted, the edges of the wound approximated, and dressed with iodol. The patient made a rapid and uneventful recovery.

The tumor was found to be a large hæmato-salpinx, with a small nucleus, which was probably nothing but a blood clot. The left ovary was not diseased.

Among the list of surgical cases were numerous ulcers of the leg, acute or chronic varicose or syphilitic. In the dispensary practice we had very good success with the use of hot water, soaking at night, and the close application of a piece of bright tin accurately fitting the ulcerating surface.

The essayist detailed several interesting cases occurring in her dispensary practice, spoke of the great benefits which she had derived from acetanilide in ovarian and congestive dysmenorrhœa, and even in labor. When given during parturition, "acetanilide regulates the pains and shortens the intervals, while apparently quieting the patient." The remarkable benefits of the same remedy in pertussis were mentioned. It seems both to mitigate the paroxysms and shorten the duration of the disease. Sulphurous acid fumigations were also tried in several cases of whooping-cough, and the results were quite gratifying. Some bad cases have done better on chloral hydrate, one grain every hour in syrup tolu, than on any other remedy.

The essayist alluded to the marked relief which she

had seen to follow the local application of hydrochlorite of cocaine (4 : 100) to the cervix uteri for the vomiting of pregnancy, and to the benefits of full doses of acetanilide (15 to 20 grains) along with sodium salicylate in acute rheumatism.

MASSACHUSETTS MEDICO-LEGAL SOCIETY.

W. H. TAYLOR, M.D., SECRETARY.

THE Twelfth Annual Meeting was held June 11, 1889, and was called to order at 11.15 A.M., by President PINKHAM. Twenty members were present. Records of the last meeting were read and approved.

Voted, on motion of MED. EXR. TOWER, that the assessment for the current year be three dollars.

DR. BENJAMIN E. COTTING, of Roxbury, was unaminously elected an associate member.

Voted, on motion of MED. EXR. DRAPER, that two members of this Society, one being the President, and the other to be appointed by him, be sent as delegates to the Section of Medical Jurisprudence of the American Medical Association, to be convened at Newport, on June twenty-fifth, next.

The President appointed Med. Exrs. Draper, Presbrey, Hartwell, Standing Committee for the ensuing year.

MED. EXR. DRAPER declined re-election, on the ground of his long service and many duties in other lines. It was voted to excuse Dr. Draper from service on this committee, and Dr. A. F. Holt was appointed a member.

A nominating committee, appointed by the President, and consisting of Med. Exrs. Munsell, Hartwell and Mead, reported the following list of nominations for officers, which was unaminously adopted:

President, Dr. J. G. Pinkham, of Lynn; *Vice President*, Dr. A. F. Holt, of Cambridge; *Corresponding Secretary*, Dr. B. H. Hartwell, of Ayer; *Treasurer*, Dr. C. C. Tower, of South Weymouth; *Recording Secretary*, Dr. W. H. Taylor, of New Bedford.

The President announced the death of Dr. Frederick Winsor, of Winchester, Medical Examiner, and former President of this Society.

DR. BENJAMIN E. COTTING read a paper entitled:

A MURDERER'S DYING CONFESSION DISPROVED BY SURGICAL AND ANATOMICAL FACTS.[1]

A girl was wounded in the head by some person who evidently intended murder. The squamous portion of the temporal bone was broken through, and the brain wounded to a depth of two inches. A large number of half-round clean cuts were seen on the scalp in the neighborhood of the fracture. The self-accused assailant stated that the wounds were inflicted by a hammer. Dr. Cotting held that this could not be the case, and that the only probable instrument was a carpenter's or a turner's gouge. The paper was a valuable and ingenious one, and was of great interest.

Discussion followed by DRS. ADAMS, WHITNEY, COTTING and others: some holding that the wounds might have been inflicted by a hammer.

DR. T. D. CROTHERS, of Hartford, Conn., read a paper on

SOME PROBLEMS OF THE MEDICO-LEGAL RELATIONS OF INEBRIETY, ILLUSTRATED BY THE CASE OF J. H. SWIFT, EXECUTED IN APRIL, 1889, FOR HOMICIDE.

Dr. Crothers held that inebriety is a brain disease, and should be ranked with insanity, as far as responsibility is concerned, in capital causes. Inebriates should be treated separately, as diseased persons. Dr. Crother's views on this subject are too well known to need further comment.

MED. EXR. F. A. HARRIS read a paper on

THE EVIDENCE IN CASES OF ARSENICAL POISONING.[2]

In a concise, clear and thorough way he gave the points necessary to prove the fact of arsenical poisoning, from the standpoint of the medical witness.

The Treasurer made his report, which was accepted.

Recent Literature.

Annual Report of the Board of Health and of the City Physician of the City of Lowell for the year 1888.

This report is creditable to those from whom it emanates, and shows that the City of Lowell is fortunate in the possession of very intelligent and efficient sanitary officials. The various subjects presented are treated with clearness and decision, but without that dogmatism which repels the wavering, the sceptical and the recalcitrant in sanitary matters.

Lowell is a great manufacturing centre and, as a consequence, a large percentage of its population consists of mill operatives, many of these living in tenement-houses or tenement-blocks, and many of them French Canadians. Moreover, in some quarters the arrangements for water supplies and sewage are in a transition stage from those of a town to those of a city; that is to say, the water pipe and the well, the vault, and the sewer are coexistent. Given these facts, it is easy to anticipate the main problems with which the health officials of Lowell are called upon to deal. Among these are the inspection of tenements and schools, the control of contagious and diarrhœal diseases, the disposal of filth, the co-operative inspection of food and water.

Since October of 1888, diphtheria and scarlet fever have been placarded, the application of cards proving acceptable rather than annoying, as a rule. The character of the population is shown by the fact that the cards are printed in French as well as in English. Diphtheria was prevalent throughout the year; of two hundred and thirty-seven cases, seventy-eight died, a mortality of thirty-three per cent.

The cases were scattered throughout the city, not manifesting a preference for any particularly unhealthy locality, though the older and more thickly settled portions of the city suffered the most.

There was no small-pox during the year. The attention of manufacturing corporations was called by circular letter, to the necessity for compliance with the statute requiring them to vaccinate all their employees who had not been successfully vaccinated within five years, with the result of securing such compliance to a large extent.

We believe no money is spent in Lowell which yields larger returns than that devoted to the health department of the city government. This report emphasizes the great need of a city hospital, and wisely suggests as a beginning the construction of wards for the isolation of contagious disease. It would be well that the dangers of a too immediate proximity of such wards to the main buildings should not be forgotten.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 19, 1889.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street, Boston.

All letters containing business communications, or referring to the publication, subscription, or advertising department of this Journal, should be addressed to the undersigned.

Remittances should be made by money-order, draft or registered letter, payable to

DAMRELL & UPHAM,
283 WASHINGTON STREET, BOSTON, MASS.

ETIOLOGY AND TREATMENT OF ACNE.

AT the recent International Congress of Dermatology and Syphilography, Barthelemy, of Paris, made a contribution to the etiology and treatment of that common cutaneous disease, acne.

He emphasized the fact that the ingestion of altered or spoiled foods, and sometimes simple indigestion, may give rise to cutaneous eruptions as urticaria. Among these eruptions, *ab ingestis*, there are inflammations of the sebaceous follicles, and it is well known that in certain subjects we may produce acne at will by the administration of iodides and bromides.

Starting from this datum it is impossible not to be struck by the relations which connect the digestive functions with acneïc eruptions.

More precise notions are now possessed concerning these relations since Bouchard published his researches on the digestive troubles and on the auto-intoxications which are the consequence of dilatation of the stomach. Barthelemy has studied the subject of acne in connection with gastrectasis. Out of 169 cases of acne, in 165 the signs of dilatation of the stomach (clapotement, etc.) were well marked. He remarks that the almost exclusive localization of acne on certain points seems to demonstrate that there is there an elective action of toxic substances, generated in the interior of the digestive tube. He adduces statistics to show that of all cutaneous diseases, acne is far the most frequent in gastrectasis. But if acne sometimes fails to appear, what is never wanting is seborrhœa, that fatty state of the skin which stains the clothing, retains the atmospheric dust, greases silk-paper, etc. We have here the direct effect of the digestive disturbance on the skin. Is the seborrhœa to be regarded as a simple hypersecretion in relation with poisonous ptomaines, or with a reflex vascular disorder? What seems to prove that we have here a simple hypersecretion is that this function commences only with puberty; that in certain women the seborrhœa almost completely gives place to the lacteal secretion, under the influence of lactation; — however this may be, we never have acne without previous seborrhœa. Dilatation of the stomach prepares the soil by enfeebling the organism, by lessening its resistance, and by producing seborrhœa.

Barthelemy insists that in acne we have an eruption which is auto-inoculable, like furuncle, impetigo, ecthyma, and like them, contagious. He has the proof of this in some observations which he has made, in which the conveyance of the disease by contagion was manifest.

Acne at its commencement is a papule, a true papule, flattened, depressed in the centre. It never becomes a pustule without the adjunction of divers microbes. In answer to the question, "What is the pathogenic element?" he says that he believes the *staphyloccus albus* to be the principle *par excellence* of these little cutaneous lesions.

If the pathogeny and history of the disease be such as has been indicated, the treatment is obvious: the dietetic regimen prescribed by Bouchard, and other modern authorities, for dilatation of the stomach, is clearly demanded. Gastro-intestinal antisepsis must be obtained by laxatives, by antiseptic powders of naphthol, prepared chalk, rhubarb, salicylate of bismuth, etc.

The general nutrition must be improved; concomitant affections, uterine, hepatic, etc. cured, and suitable tonics administered, to which cod liver oil will often prove an important adjunct. Remedies to prevent gastro-intestinal fermentations, as hydrochloric acid and pepsin, are often indicated, Sulphur baths and cold bathing as reconstituents have a certain utility.

But to gastro-intestinal antisepsis should be joined tegumentary antisepsis. The proper agents forfulfilling this end are the carbolic sprays, antiseptic soaps with sublimate, borax, naphthol, the application of ointments or epithems, such as the phenico-sulphuretted paste, salicylo-boric plaster with oxide of zinc, frictions with black soap, counselled by Laithe, — these, with camphoretted alcohol, are useful. In certain cases the external treatment becomes predominant; as when the acne-papules, like the lesions of scabies or smallpox, have been invaded by the pyogenic microbes, and the inflammation, bursting the barriers of the glandular tube, has spread to the surrounding cellular tissue; recourse then should be had to the red-hot platinum wire, or to punctiform electric cauterizations. This method, when applied to the face, should be practised with extreme caution, so as not to leave scars. Abscesses should be treated on general antiseptic principles.

It will be seen from the above abstract that the French dermatologist has a hobby of his own with regard to the pathogeny and treatment of acne. It is not probable that other observers will see so necessary a connection between states of the stomach (and especially gastrectasia), and acneïform eruptions, particularly those of puberty. It will, at any rate, be worth the while for physicians, profiting by the experience of M. Barthelemy, to state their cases of

acne, and in particular those that have proved rebellious to all the ordinary modes of treatment, from the stand-point which he has indicated; possibly they may now and then find digestive disturbances the *fons et origo mali*.

THE APPROACHING MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

As will be seen by a notice in another column, the American Public Health Association is to hold its annual meeting at the Brooklyn Institute from October 22d to 25th. The topics named for consideration include such important ones as the Causes and Prevention of Infant Mortality; Railway and Steamship Sanitation; Methods of Scientific Cooking; the Prevention and Restriction of Yellow Fever; Tuberculosis and Diphtheria; Compulsory Vaccination; and "Sanitation of Asylums, Prisons, Jails and other Eleemosynary (*sic*) Institutions."

The Sanitary Exhibition in connection with the meeting is to be made a feature of great interest; and we are glad to observe is to be open to the general public October 22d, and to remain open till December 1st. The articles exhibited are divided into nine divisions, having reference respectively to the Dwelling, Schools and Education, Factories and Workshops, Clothing and Dress, Food, Sanitary Engineering, Public Health Administration in Cities and Towns, the Laboratory, and the Red Cross Section. In some of these divisions there are many classes. For example, under the Dwelling, we have — Dwellings; models and designs for sanitary dwellings. Treatment of the site: foundations, drainage, drainage tiles, etc. Materials for construction: bricks, tiles, floors, cements, etc. Heating: devices and appliances for furnaces, stoves, water and steam heating apparatus. Ventilation. Lighting. Domestic water supply: purification, filters, water fittings, etc. Plumbing: traps, sinks, water closets, baths, etc. Disposal of waste: domestic garbage destructors, garbage receptacles, etc. Sanitary furniture, refrigerators, wall paper (non-arsenical), floor coverings, etc.

Under the division of food, we have — Selected displays of unprepared animal and vegetable substances used as food or in the preparation of food. Prepared vegetable substances used as food, including canned and prepared, and preserved fruits and vegetables; prepared cereals, meals, flour, biscuits, bread, etc.; syrups, sugars, etc. Prepared animal substances used as food: canned, smoked, salted, preserved and prepared animal foods, including honey. The dairy: products of the dairy. Beverages of all kinds: alcoholic, non-alcoholic, tea, coffee, cocoa, chocolate, etc. New varieties of food: food for infants and invalids. Articles and devices used in the preparation of food: cooking-stoves, ranges, etc.; vessels for preserving food, etc. Adulterants and adulteration.

The expense of the exhibition is to be defrayed by an assessment upon each exhibitor; and at the close of the exhibition the Association will award its diploma to meritorious articles, on the recommendation of expert judges.

It is to be hoped that the attendance upon this meeting will be as great as the interest of the subject merits.

CORRELATIVE PROGRESSION OF ALCOHOLIC LUNACY AND GENERAL PARALYTIC DEMENTIA.

AT the recent International Congress of Mental Medicine, Garnier presented some statistics showing that the number of insane in Paris has increased the past few years in alarming proportions, the admissions to the asylums being thirty per cent. greater the last six years than during any similar previous term.

Mental alienation is more common in the male than in the female (males 55.61 %; females 44.38 %). More people become insane in the spring months than in any other season of the year; the maximum of frequency of the various forms of insanity may be said, however, to be in June.

The numerical increase of the last few years is, above all, due to the fact that there are two morbid types whose frequency is in very rapid progression: alcoholic lunacy and general paralysis. The essential psychoses, such as mania, melancholia, chronic delirium or progressive systematized psychosis, remain almost stationary, and are, in general, twice as common in the female as in the male. The progression of alcoholic insanity is so rapid that its frequency is twice as great to-day as it was fifteen years ago. To alcoholism is due, at the present day, almost one-third of the cases of mental alienation observed at the special infirmary.

The observations of the delirious forms of alcoholic insanity shows that the reactions which develop under its use are from day to day more violent, more dangerous to life, consequences which it is proper to attribute to the toxic character of the alcohols actually in use.

General paralysis, which is, with alcoholic insanity, the morbid form whose increase has gone on at the most rapid rate, figures for twelve per cent. in the totality of patients registered at the depot. In fifteen years its frequency has more than doubled.

Charts were shown at this meeting which made plain the simultaneous increase of alcoholic insanity and general paralysis, proving also that their progression is correlative. "In the solidarity of their invading march," said Dr. Garnier, "appears clearly demonstrated the etiological influence of alcoholism on the development of interstitial encephalitis."

MEDICAL NOTES.

— Schultze points out that it is far better to use two fingers for vaginal examination, not only because the middle finger is longer than the index, but still more because with two sensitive surfaces, the relative position of which can be varied, we can find infinitely more than with one.

— Denver, Colorado, has just completed a $30,000 hospital.

— The first general meeting of the Continental Anglo-American Society will take place at the Grand Hôtel, Paris, on Monday, September 30th, at 5 P.M., and the first annual dinner will also take place at the Grand Hôtel at 8 P.M., on the same evening. The following gentlemen are honorary Presidents of the Society: Sir Spencer Wells, Sir Joseph Lister, Dr. Richard Quain, Professor Ball, Professor Brown-Séquard, Dr. Ricord, Dr. J. S. Billings, Dr. Fordyce Barker, and Dr. Weir Mitchell.

— Dr. Thomas King Chambers, the author of "Manual of Diet and Regimen in Health and Disease," has lately died in England. Life-long ill-health (due to the recurrence of aneurism, first of the left popliteal artery, then of the right, and finally of both carotids, accompanied by heart disease,) prevented his taking the part in active medical practice which his ability and energy entitled him to.

— The Southern Surgical and Gynecological Association will meet in Nashville, Tenn., November 12th, 13th and 14th, 1889. A preliminary programme has been issued announcing thirty-five titles. Hunter McGuire, M.D., LL.D., Richmond, Va., *President;* W. E. B. Davis, M.D., Birmingham, Ala., *Secretary.* Members of the Medical Profesion are cordially invited to attend.

— At the last meeting of the Faculty of the Medico-Chirurgical College, Dr. Ernest Laplace, of Philadelphia was appointed Professor of Pathology. Professor Laplace is a native of New Orleans, and a graduate of the Literary Department of the Georgetown University, D. C. After several years' study in Tulane University and the Charity Hospital he went abroad and graduated in the "Faculté de Medicine de Paris," where he studied under Pasteur and Cornil. Dr. Samuel Wolfe, of Skippack, Pa., will fill the chair of Physiology for the coming year.

— Dr. James Crichton Browne's address before the Psychological Section of the British Medical Association was upon the "Hygienic Uses of the Imagination." He dwelt upon the uses of fiction in soothing the mind and giving it a proper mental balance. Contrary to the usual belief that the imagination is most active among the insane, he said that, as a rule, the lunatic is as dull as a stone. "He is the victim of a fixed idea, or his delusions occur in groups so unvarying that having ascertained one of them you can predict the rest." As "idiocy is the absolute negation of imagination, and insanity undermines and destroys it more or less," it is important that the imagination should be evoked.

— The recent death by suicidal hanging, in Illinois, of Dr. David Tilton Brown, formerly superintendent of the Bloomingdale Asylum, N. Y., is reported to have been caused by the chagrin due to the publication by a reporter of a New York daily paper of the fact of Dr. Brown's identity with the former well-known alienist. Through overwork and a close application to that special branch of mental study, his own mind became affected and signs of insanity appeared. It was at the time supposed by many persons that Dr. Brown had died; but he had really been taken away to a quiet place, and was undergoing treatment when the reporter discovered the fact and forced his way into the presence of the retired physician, after which, says a writer in the *Boston Advertiser*, he wrote a highly sensational report of his proceeding. Much criticism was made at the time of the publication of this report, and much fear was expressed concerning the effect which the publication would have upon Dr. Brown. The fear was justified. He was so mortified and distressed concerning the event that he has just ended his life with his own hand.

— Yellow fever is reported as raging at Vigo, in the province of Pontevedra, Spain. Two cases of cholera, one of which has terminated fatally, are also reported to have occurred in Hungary near the Austrian frontier. Cholera appeared in Mesopotamia, as shown by the following dispatch published in the Marine Hospital Service *Bulletin* under date September 13.

"Cholera, since July 27th, made its entry into Mesopotamia in as mysterious a manner as it made its appearance into Egypt in 1883. It is certain that it penetrated from Bombay via Bassora; it could not as yet be determined how. Perhaps, as in Egypt, through Arabian stokers (firemen), who are employed on the English steamers of the Bassora-Bombay Line, and who, upon their arrival at Bassora, go to their homes. At first cholera appeared at Schatra (3,000 inhabitants), two and a half days' journey from Bassora, at the Schatel-Hay Canal, which connects the Tigris with the Euphrates River. In a few days from July 27th to August 6th, 308 persons died. On the 1st of August it appeared at Naszric (8,000 inhabitants), southerly from Shatra near the embouchure of the Schatel-Hay into the Euphrates — a city which was founded in 1872, by Natir Pasha, the Montefik sheik. From the 1st to the 9th of August, 293 deaths occurred — on the 8th of August, so many as 85. The houses are situated upon the flat marsh land, and are only reed huts. The inhabitants carry on the culture of rice and some cattle raising. It finally made its appearance at Bassora on August 6th, and at first an Arabian girl died who had come there ten days before from Filie in Persia. On August 9th, 15 deaths occurred there. The reports of Gazala, the sanitary physician, do not allow any doubt to arise as to the diagnosis."

BOSTON AND NEW ENGLAND.

— The Quarterly Meeting of the Rhode Island Medical Society was held at Providence, September 12, about 80 members attending.

— The will of Mrs. Ellen M. Gifford, of New Haven, who died recently, after giving legacies of about $150,000 to her own and her husband's relatives, and $50,000 to various friends, leaves the rest of her property to charitable objects. The New Haven

Hospital gets $50,000, with power to the executors to increase it to $90,000; the New Haven Dispensary, $5,000; the New York Society for the Prevention of Cruelty to Animals, $50,000; the Massachusetts Society of the same name, $25,000, and $30,000 for the support of a home for stray and suffering animals at Boston; the New York Society for the Relief of the Ruptured and Crippled, $25,000; the Connecticut Prison Association, $5,000; the New Haven Society for the Prevention of Cruelty to Animals, $5,000; the Massachusetts General Hospital, $10,000; the McLean Insane Asylum, $5,000; the Boston Port and Seaman's Aid Society, $5,000; the Massachusetts Society for Aiding Discharged Convicts, $5,000; for aiding poor, sick, and incurables, $20,000; the New York Society for the Prevention of Cruelty to Children, $5,000; the New York Society for the Relief of the Destitute Blind, $5,000; the New York Colored Home and Hospital, $5,000; the Washington Society for the Prevention of Cruelty to Animals, $5,000; the New Hampshire Society for the same object, $5,000, and the Massachusetts Society for the Prevention of Cruelty to Children, $5,000.

Miscellany.

NEW YORK PHYSICIANS MUST BE ABLE TO READ AND WRITE.

A recent law passed by the New York State Legislature adds to the advancement of the preliminary training of the medical students. It reads: "Before the Regents of the University of the State of New York, or the Trustees of any Medical School or College within this State, shall confer the degree of Doctor of Medicine upon any person who has not received a Baccalaureate Degree, in course from a College or University duly authorized to confer the same, they shall require him to file with the Secretary or recording officer of their University or College, a certificate showing that prior to entering upon the prescribed three years' study of medicine he passed an examination conducted under the authority and in accordance with the rules of the Regents of the University of the State of New York, in arithmetic, grammar, geography, orthography, American history, English composition, and the elements of natural philosophy, and such certificate shall be signed by the Secretary of the Regents, and countersigned by the Principal or Commissioner conducting the examination."

MILK EPIDEMICS.

Now that so much public attention has been drawn to the dependence of epidemic diseases upon milk supplies, it is not surprising, and, indeed, it is satisfactory to find that close watch is kept upon all such possibilities by those engaged in public health administration. There have been recently two important inquiries in England, says the *Medical Press and Circular*, into milk infection, by Dr. Page and Dr. Parsons respectively. In the former case, scarlet fever and enteric fever were ascribed at Spennymoor, in Durham, to milk, and although there was much *primâ facie* suspicion, Dr. Page concluded finally that it was an instance of coincidence merely. Thus, the scarlet fever was practically endemic, and depended on matter-of-fact methods of spread, whilst the enteric fever, though slightly prevalent at the farm whence the milk came, was not judged to be directly dependent on this, but to be due to other unwholesome conditions. In Dr. Parsons's most interesting inquiry into scarlet fever "with associated diphtheria and sore throat" at Macclesfield, where some very interesting clinical features were brought out, there was no question as to the causation by a certain milk supply of the complex affection observed. Elimination of other sources of infection narrowed the question down to the milk of a newly-calved cow, which had come into the supply just before the major outbreak of the epidemic. That this had to do with it there was no question; but here investigation of the problem came to a standstill, for no disease of udders or coats could be definitely made out. The case, however, closely resembles those of Power's well-known inquiries at Hendon and elsewhere; and our contemporary thinks that probably Dr. Parsons is correct in his conjecture as to the influence of the puerperal condition of the cow in developing the potentiality of human infection.

CONVENTIONAL MOURNING OR HEALTH?

The *New York Medical Journal* asks this pertinent and important question and then discourses the subject.

"Which shall it be? The time has come to choose. Unmitigated mourning must go. A movement has been started in England to put an end, if possible, to the present irrational mourning costumes that exact of women great personal inconvenience, physical injury, and disastrous expense. The conventional costume of a well-bred widow, for instance, possesses every known quality of unhygienic, non-æsthetic, and costly dress. Proper exercise while she is wearing it is out of the question. Seclusion is secured in ways less barbarous perhaps than inducing deformity of the feet, yet our occidental mourning customs effectually keep women within doors. The heart of the stoutest warrior might quail within him if a quiet stroll required the wearing of two crape veils, each six feet long originally and only slightly shortened, but not lessened in weight, by a hem half a yard deep — one veil to be worn over the face and the other to hang down the back! The widow's gown must be inconveniently long, the outside garment must cling, and both must be made of inelastic, non-inspiring material. Add to this that within, which passeth show, and the picture is pretty black. The husband who loses his wife escapes such outward trappings, not being forced to adopt any special habiliments that can incommode or injure him. A simple band around the hat announces the fact of his changed circumstances and secures freedom from idle questions. Strange inconsistency of custom that thus discriminates between men and women, and always to the disadvantage of women in point of health!

"In this new crusade of common sense Lady Harberton takes the lead, setting forth in a recent article the reasons why existing mourning costumes should

be abandoned by all sensible women. The materials now in use are in themselves injurious, the dyes being often of a poisonous nature and frequently injuring the skin and ruining the complexion. What woman who indulges in conventional mourning escapes the staining process resulting from damp crape? Only the victim can know the energy and perseverance required to remove from brow and neck the literal clouds that gather from such a cause. The harm to the exterior of the body is easily perceived. Not less injurious is the irritation to the respiratory tract caused by minute loose particles of poisonous crape. To the pang of separation is added the thought that our loved ones are condemned to suffer physical discomfort for a year or two, and, possibly, disease for an indefinite period. . . .

"The moral influence of mourning is even more to be deplored than its physical effects. Gloomy garments, darkened rooms, all the subdued life of the house of mourning, depress the powers, lower vitality, and absorb an undue quantity of domestic ozone. Such unwise fashions tend to stultify the wonderfully recuperative powers of time and nature. Hugging grief to keep it warm is a poor business, and so is the worship of sorrow. Speed the day when it shall be considered unbecoming to wipe our eyes upon the public, or to dust our neighbors' shelves with any personal woe! All that Diogenes asked of Alexander was that the king should stand out of his sunshine. And we all have a right to demand of society that it take its mourning out of humanity's sunshine."

NOTE ON INTRA-THORACIC GROWTHS DEVELOPING FROM THE THYROID GLAND.

DR. WILLIAM OSLER, of the Johns Hopkins University, writes in the *Medical News* of September 7th, regarding the development of intra-thoracic growths from the thyroid glands. It has been shown, he says, that portions of thyroidal tissues may be met with anywhere from the base of the tongue to the heart, and in regions lying between these points the so-called struma tumors may be found, or even in rare instances within the trachæ. Thyroidal growths also occur within the thorax most commonly sub-sternal in position, and connected directly with the gland. Of these a number have been described (Virchow, *Geschwülste*, bd. 3). More rare tumors develop from the deeper portions or aberrant bits of a lateral lobe and extend into the chest, forming large intra-thoracic growths.

A most remarkable case is quoted from Dettrich (*Prager med. Wochenschrift*, No. 31, 1887). In a woman aged sixty, who had suffered for some time with cough and hæmoptysis, there was found, filling the greater part of the right side, a cystic tumor the size of a man's head. It was covered by the parietal pleura and naturally caused great compression of the lung. Above it was connected with the right lateral lobe of the thyroid. The cyst had yellowish brown contents, and contained cholesterin. Kretschy (*Wiener med. Wochenschrift*, 1877) describes a sarcoma of the thyroid, four and three-quarters inches in length, which formed an extensive mediastinal tumor passing to the level of the ninth dorsal vertebræ.

In the following case, No. 702, Post-mortem Records, Montreal General Hospital, there was a tumor similar in situation to Dettrich's, though not so large.

The patient, a woman had died with symptoms of purulent bronchitis. There was no special emaciation. Occupying the top of the left thoracic cavity, outside the pleura, was a mass the size of a large orange, closely attached to the œsophagus. The arch of the aorta lay on the right side, the left subclavian passed directly over it, and the left carotid passed just beside it. There was no special connection with any thoracic organ, though filling completely the top of the left thorax. There was a large bronchocele, the left lobe of which was in contact with the tumor and could not be isolated from it.

On section, it consisted of a series of imperfectly separated cysts containing a yellow brown fluid in which were plates of cholesterin. The upper part of the tumor was firm and hard; some of the septa had calcified, others had a fibro-cartilaginous consistence.

The relations of this mass, its anatomical character, and the nature of the contents of the cysts, identical with that which is found in so many cases of old bronchocele, left no question that it had developed from an outlying lobule of the left thyroid.

In connection with the case of Kretschy, above referred to, Dr. Osler refers to a similar instance reported by him a few years ago (*Montreal General Hospital Reports*, Vol. 1, 1880):

A girl, aged sixteen, had been under treatment for what appeared to be ordinary bronchocele. It had grown with great rapidity. There was marked difficulty in breathing, and the question of tracheotomy was considered, but as the dyspnœa became easier the operation was deferred. Death occurred suddenly. Post-mortem, a tumor was found which involved exclusively the left lobe of the thyroid, and formed a large round mass eight inches in circumference; above it extended to the level of the thyro-hyoid ligament, while below it passed down beside the trachea to the bifurcation. From behind, the mass had an elongated somewhat oval shape; the lower end rested upon the left bronchus. Along this surface it measured one and three-quarters inch in length. At the upper right angle of the mass in front was a small thin remnant of the left lobe capping the tumor, the tissues of the two blending, not separated by a capsule. The right lobe of the thyroid was of normal size and appearance. Histologically the growth consisted of small lymphoid corpuscles.

This case was reported as one of lympo-sarcoma of the deep cervical glands involving the thyroid, and simulating goitre, but the author now has no doubt that it was a case similar to Kretschy's, in which the growth developed from a thyroidal lobe with extensions down the trachea.

Correspondence.

QUACK MEDICINE IN GERMANY.

BOSTON, June 17, 1889.

MR. EDITOR, — To those who regard with admiration the "paternal" governments of Europe, I beg leave to present the following extract from a recently issued work:

Referring to the political methods of Bismarck, we read that, "In the Fatherland the Government charges itself with watchful solicitude for the morals of its subjects. But as even Homer sometimes nods, so the most vigilant of Administrations sometimes fails to discover that the columns of German newspapers are defiled by the in-

sertion of advertisements of immoral pills or by the addresses of unclean doctors. Where, however, any newspaper continuously opposes itself to the will of the authorities, the custodian of public morals puts on his spectacles, and woe betide the unfortunate journal, if, in the obscurest corner of his badly-printed page, there should be discovered lurking an allusion to the objectionable pill or the disreputable physician. The Administration is down upon him at once, and punishment is heaped on punishment until the editor consents to dance to the piping of Power. Then the custodian of public morals once more slumbers and sleeps, and the quack advertises his pills in peace."

Although the above is written especially in reference to the methods of government as forming and guiding public opinion on matters of world-wide importance, as well as on the action of private individuals in relation to those in power, the philosopher in medicine may see wherein the health and morals of the single citizen, and consequent welfare of the state, are involved. Very respectfully,

F. B. STEPHENSON, M. D.
Surgeon U. S. N., A. A. S.

Deaths reported 2,260: under five years of age 967; principal infectious diseases (small-pox, measles, diphtheria, and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 511, consumption 291, acute lung diseases 138, diarrhœal diseases 314, diphtheria and croup 74, typhoid fever 72, whooping-cough 27, scarlet fever 8, cerebro-spinal meningitis 8, measles 4, erysipelas 4. From whooping-cough, New York 15, Philadelphia 5, Cambridge 2, St. Louis, New Orleans, Worcester, Fall River and Springfield 1 each. From scarlet fever, New York and Philadelphia 3 each, Baltimore and Lawrence 1 each. From cerebro-spinal meningitis, New York 2, Philadelphia, Boston, Washington, Worcester, Springfield and Quincy 1 each. From measles, New York 2, Lowell and Salem 1 each. From erysipelas, New York 3, St. Louis 1. From malarial fever, New Orleans 11, Philadelphia 5, New York 4, Baltimore and Fall River 2 each, Nashville 1.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,555,406 for the week ending August 10th, the death rate was 18.8. Deaths reported 3437: Infants under one year 1259. Acute diseases of the respiratory organs (London) 149, diarrhœa 548, whooping-cough 60, measles 58, scarlet fever 52, diphtheria 38, fever 29. The death rates ranged from 13.9 in Oldham to 34.6 in Preston, Birmingham 18.7, Bradford 19.5, Hull 21.6, Leeds 20.3, Leicester 20.5, Liverpool 19.2 London 16.4, Manchester 24.5, Newcastle-On-Tyne 30.8, Nottingham 18.0, Sheffield 23.9, Sunderland 28.4.

In Edinburgh 15.1, Glasgow 21.0, Dublin 24.8.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,555,406, for the week ending August 24th, the death-rate was 17.2. Deaths reported 3,151: infants under one year of age 1,085; acute diseases of the respiratory organs (London) 115, diarrhœa 394, whooping-cough 60, scarlet fever 50, diphtheria 49, measles 41, fever 41, small-pox (Leeds) 1.

The death-rates ranged from 11.1 in Brighton to 34.0 in Plymouth: Birmingham 15.9, Bradford 12.4, Hull 23.6. Leeds 15.8, Leicester 18.0, Liverpool 19.0, London 14.9, Manchester 24.4, Norwich 14.9, Nottingham 15.4, Sheffield 21.5.

In Edinburgh 14.7, Glasgow 20.9, Dublin 25.1.

In the twenty-eight greater towns of England and Wales with an estimated population of 9,555,406, for the week ending August 31st, the death-rate was 169: deaths reported 3,091: infants under one year of age 929; acute diseases of the respiratory organs (London) 148, diarrhœa 296, whooping-cough 60, diphtheria 52, scarlet fever 51, measles 48, fever 36.

The death-rates ranged from 9.0 in Derby to 29.7 in Wolverhampton: Birkenhead 20 9, Bradford 20.4. Bristol 16.4, Hull 21.3, Leeds 17.8, Leicester 9.7, Liverpool 19.7, London 15.1, Manchester 23.4.

In Edinburgh 16.2, Glasgow 19.3, Dublin 26.6.

The meteorological record for the week ending Sept. 7, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 7, 1889, TO SEPTEMBER 13, 1889.

With the approval of the Secretary of War, the leave of absence granted Major JOHN H. JANEWAY, surgeon, in S. O. 52, July 29, 1889, Division of the Pacific, is extended two months. Par. 1, S. O. 206, A. G. O., September 5, 1889.

By direction of the acting Secretary of War, the leave of absence on surgeon's certificate of disability granted First Lieutenant FREEMAN H. WALKER, assistant surgeon in S. O. 92, April 20, 1889, from this office, is extended one month on surgeon's certificate of disability. S. O. 211, A. G. O., September 11, 1889.

SOCIETY NOTICE.

AMERICAN PUBLIC HEALTH ASSOCIATION. — The Seventeenth Annual Meeting will be held in the Hall of the Brooklyn Institute, Washington and Concord Streets, Brooklyn, October 22, 23, 24 and 25, 1889. Addresses of welcome will be delivered by Hon. Alfred C. Chapin, Mayor, on behalf of the city, and by Alexander Hutchins, M.D., on behalf of the medical profession

The following topics have been selected for consideration at the meeting: (1) The Causes and Prevention of Infant Mortality. (2) Railway Sanitation. (*a*) Heating and ventilation of railway passenger coaches; (*b*) water-supply, water-closets, etc.; (*c*) carrying passengers infected with communicable diseases. (3) Steamship Sanitation. (4) Methods of Scientific Cooking. (5) Yellow Fever. (*a*) The unprotected avenues through which yellow fever is liable to be brought into the United States; (*b*) The sanitary requirements necessary to render town or city proof against an epidemic of yellow fever. (*c*) The course to be taken by local health authorities upon the outbreak of yellow fever. (6) The Prevention and Restriction or Tuberculosis in Man. (7) Methods of Prevention of Diphtheria, with Results of such Methods. (8) How far should Health Authorities be permitted to apply known Preventive Measures for the Control of Diphtheria. (9) Compulsory Vaccination. (10) Sanitation of Asylums, Prisons, Jails and other Eleemosynary Institutions.

Exhibition of sanitary goods and appliances in another large hall close by.

J. H. RAYMOND, M.D.,
Chairman Executive Committee.

OBITUARY. ADDINELL HEWSON, M.D.

Dr. Addinell Hewson, a distinguished physician and author, died at his residence in Philadelphia, 1434 Spruce Street, September 11th, in his sixty-first year. He was a graduate of Jefferson College in 1850, and subsequently pursued his studies in Paris and Dublin. He was at one time resident physician at the Pennsylvania Hospital, and visiting surgeon at the Episcopal, Willis Ophthalmic, and Pennsylvania Hospitals. He was the author of numerous works on surgery.

OBITUARY. THOMAS L. REED, M.D.

Dr. Thomas L. Reed, formerly a prominent physician of Philadelphia, died suddenly from angina pectoris at Cape May, September 11th. He has been subject to acute attacks of the ailment which proved fatal, and his death was brought on by over-exertion. Dr. Reed was born in 1822, and was a self-made man. When twelve years of age he entered the employ of a large grocery store, and at odd hours spent his time in educating himself. He subsequently taught school for several years, saved enough money to study medicine, and graduated from the Jefferson Medical College in 1846. When he retired, in 1871, he had a large practice, and was ranked among the foremost of Philadelphia's physicians.

BOOKS AND PAMPHLETS RECEIVED.

Notes on the Electro-Magnet in Ophthalmology, with a Report of Nine Cases. By Wm. Ellery Briggs, M.D. Reprint. 1889.

Sixth Annual Announcement of the Medical and Dental Department of the National University. Washington, D. C. 1889-1890.

The Treatment of Fractures of the Neck of the Femur by Immediate Reduction and Permanent Fixation. By N. Senn, M.D., Ph.D., etc. Reprint. 1889.

Index Catalogue of the Library of the Surgeon-general's office, United States Army. Authors and subjects. Vol. X, O-Pfutsch. Washington: Government Printing Office. 1889.

On Disordered Digestion and Dyspepsia. By Frank Woodbury, A.M., M.D., Fellow of the College of Physicians of Philadelphia, etc. Detroit, Mich.: George S. Davis. 1889.

Transactions of the American Surgical Association, Vol. VII. Edited by J. Ewing Mears, M.D. Philadelphia: Printed for the Association and for sale by P. Blakiston, Son & Co. 1889.

A Manual of Chemistry for the use of medical students. By Brandreth Symonds, A.M., M.D., assistant physician to Roosevelt Hospital, etc. Philadelphia: P. Blakiston, Son & Co. 1889.

A Laboratory Guide in Urinalysis and Toxicology. By R. A. Witham, A.M., M.D., Professor of Chemistry and Physics in the Medical Department of the University of City of New York, etc. Second edition. New York: William Wood & Co.

Text-Book of General Therapeutics. By W. Hale White, M.D., F.R.C.P., Senior Assistant Physician to and Lecturer on Materia-Medica and Therapeutics at Guy's Hospital. With illustrations. London and New York: Macmillan & Co. 1889.

Prolapse of the Womb. With especial reference to the (so-called) Hypertrophic Elongation of the Supra-Vaginal Portion of the Cervix. with Report of a Case. By Lewis H. Adler, Jr., M.D., late Resident Physician University Hospital, Philadelphia. Reprint. 1889.

Spinal Caries: Operative Treatment. Laminectomy or so-called Trephining of Spine. By De Forest Willard, M.D., Ph.D., Clinical Professor of Orthopedic Surgery in the University of Pennsylvania, surgeon to Presbyterian Hospital, etc. Reprint. Philadelphia, 1889.

Lectures on Obstetric Nursing. Delivered at the Training School for Nurses of the Philadelphia Hospital. By Theophilus Parvin, M.D., Professor of Obstetrics and Diseases of Women and Children at Jefferson Medical College; Obstetrician to the Philadelphia Hospital. Philadelphia: P. Blakiston, Son & Co. 1889.

A Text-Book of Human Physiology, including Histology and Microscopical Anatomy, with special reference to the requirements of Practical Medicine. By Dr. L. Landois, Professor of Physiology and Director of the Physiological Institute, University of Greifswald. Third American, translated from the sixth German edition, with additions by Wm. Stirling, M.D., Sc. D., Brackenburg, Professor of Physiology and Histology in the Owens College, and Professor in the Victoria University, Manchester. With 692 illustrations. Philadelphia: P. Blakiston, Son & Co. 1889.

Addresses.

PRESIDENT'S ADDRESS. AMERICAN DERMATOLOGICAL ASSOCIATION.[1]

BY J. E. GRAHAM, M.D., TORONTO.

GENTLEMEN, — It is a subject for congratulation that the Thirteenth Annual Meeting of this Association should be held in Boston. The science of dermatology has been cultivated here in a pre-eminent degree. The years 1868, 1869, and 1870, mark an era in the history of the specialty on this continent. During those years a general interest in the subject seems to have sprung up in many of our larger cities, and it will be seen from the following facts that Boston was at that time one of the principal centres of activity: —

"In 1868 the Boston City Hospital opened an outdoor department in charge of Dr. Howard F. Damon, where, during the first decade, twelve thousand patients were treated. The Massachusetts General Hospital likewise inaugurated an out-patient department for skin diseases in 1869, Dr. J. C. White receiving the appointment. Here, during the first ten years, between nine and ten thousand cases were recorded."

Harvard University was among the first to institute a chair in dermatology.

Dr. Duhring, in his address delivered at the third annual meeting of this Association, makes the following reference to the earliest dermatological literature published on this continent: [2]

"According to Thacher the first medical publication of any kind in New England, and we may safely assert on this continent, was a brochure, entitled 'A Brief Guide in the Small Pox and Measles,' the author being Thomas Thacher, a noted divine as well as a learned physician of Boston, published in 1677. Other small works, as those of Colman, Boylston, and Williams, all of Boston, shortly followed."

To our first president and to his colleagues here, we, as an Association, owe much of our success in the past. It is therefore to be hoped that as we are gathered together in a city, which in some respects may not inappropriately be called the birthplace of dermatology on this continent, our meeting may be noted for zeal and unanimity of action in scientific work.

In an address such as this it is a difficult matter to select a subject that has not already been dwelt upon, and which would at the same time be of general interest. In reading over the proceedings of this Association for the past twelve years, I was struck by the enormous amount of work done by many of the members, as evidenced by the papers read. Several of the departments in the dermatological field appear to have been subjected to the keenest observation and criticism. The subject which perhaps of all others has been the least adverted to is the Prevention of Skin Diseases. Doubtless one of the reasons for this is that in these days we have our State, Provincial and National Associations, whose duty it is to investigate the causes of disease and to suggest the best means for their prevention. The Sanitary Association, however, look to the medical profession for their principal support, and it is to the honor of the profession that this support has always been given in the most generous and self-sacrificing way.

I am led by these considerations to make a few remarks upon the prevention of some forms of skin diseases, and especially that form of prevention which necessitates the enactment of sanitary laws. Passing over the exanthemata, the prevention of which has already been dealt with by our sanitary legislators, two diseases will be adverted to, which, although not dangerous to life, are disagreeable enough, and the cure of one of them sufficiently difficult to make the study of their prophylaxis a matter of importance, namely, scabies and tinea tonsurans.

Dr. J. C. White, in a paper upon the treatment of the former disease, written on account of its then great prevalence in this city, made the following remarks: "As to the general control of this affection in its well-nigh epidemic state of prevalence, it is only by drawing the attention of the profession to this activity, and to the best methods of destroying it in individual cases, that we may hope to accomplish anything."

In case of such state of prevalence would not the course of the epidemic be shortened if, instead of waiting for patients to apply for treatment, the children in the public schools and the workers in factories were inspected by competent physicians, and if necessary at once placed under treatment? In fact, I have learned that such regulations were enforced in one of our provincial towns with very successful results.

The spread of tinea tonsurans, particularly in orphan asylums, is a subject which should receive more attention than is at present given to it. This is a disease which in any case is difficult to cure, but is much more obstinate when it breaks out in a public institution. One who has had experience of the expense, labor and general worry connected with its management under such unfavorable circumstances, will appreciate the importance of the establishment of stringent regulations whereby all boys and girls admitted into orphan asylums should be carefully examined and reported upon by a competent physician before they are allowed to become inmates. Instances have no doubt occurred within the knowledge of many of us where the disease has existed for years in such homes, causing great expense and trouble, when the whole might have been prevented if proper regulations had been enforced.

I shall now refer to two diseases to a greater or less extent preventable, which in importance far surpass those already alluded to, namely, syphilis and leprosy.

When we consider that syphilis is so widely spread on this continent that its *innocent* victims may be numbered by thousands, it might at first appear surprising that so far few attempts have been made to eradicate it or even to check its progress. This history of prevention, as it has been tried in different countries, reveals the great difficulties which stand in the way and makes us hesitate before recommending any particular course. The history of success and failure of such laws in Denmark, for instance, will illustrate this point. The question has been one to which the various governments of that country have for centuries given a great amount of attention. The success of their more recent legislation, although in many ways encouraging, has not been such as was at first expected. Notwithstanding the fact that laws of this character have been for some years in force in Paris, the victims of syphilis are still very numerous, as shown by hospital statistics. These incomplete

[1] Delivered at the Thirteenth Annual Meeting, Boston, September 17, 1889.

[2] Transactions of the American Dermatological Association, 1879.

results arise largely from imperfect registration and as a consequence clandestine prostitution.

In England the Contagious Disease Acts, although not repealed, were divested of any power for good by a resolution passed by the House of Commons in 1883. The Acts were supported by the most eminent members of the profession, and if they had been continued and extended would have doubtless have done good service in the prevention of syphilis. In the report of a Royal Commission, appointed in 1870 to look into their working, the following statement appears:

"The Acts have purged the towns and encampments to which they have been applied of miserable creatures who were masses of rottenness and vehicles of 'disease.'

"We are satisfied from the evidence that the frequent examination of women is the most efficacious means of controlling the diseases."

Notwithstanding this and other strong evidence in favor of the Acts, they were practically repealed on account of persistent opposition from an influential class of the community.

From the history of sanitary legislation in this matter, the inference may fairly be drawn that if a thorough registration and periodical examination of prostitutes were made the ravages of syphilis would thereby be much diminished. It appears to be extremely difficult to effect such thorough registration, and like other laws of the kind unless well administered they had better not be placed in the Statute Book. It is unwise to advocate any legal measures and hope for their success if a large and important section of the community, from conservative motives, directly and vehemently oppose them. This opposition may to our minds seem unreasonable, but the fact of its existence is sufficient to make one hesitate in such a line of action. The great difficulties which surround this subject ought not to deter earnest and thoughtful men from attempting to grapple with them. The importance of the question is such as to demand the greatest intelligence for its solution.

There are, however, some methods of prevention about which there can be little or no difference of opinion, and which members of this Association have done much to further. All will agree that the early diagnosis and successful treatment of syphilis, both in males and females, will have a positive effect in checking the spread of the disease. To this end it is necessary that our medical students should, during their course, devote to it a careful and systematic study. Even in our larger medical colleges, where ample opportunities are given for this course of instruction, it is to be feared that a great number of students do not sufficiently appreciate the importance of the subject to take advantage of such opportunities. Many expect to practice in country districts, and make a great mistake when they think they will not meet with this affection in out-of-the-way places. Some of the worst cases of contagion are reported from small towns, and no doubt all of us have seen cases of unrecognized syphilis sent from country districts. Judging from the announcements of our smaller medical colleges we are afraid that in some of them little attention is paid to this subject.

Next in importance to the early diagnosis of the disease is the provision of free and abundant facilities for its successful treatment in hospitals. This is a work in which all classes of the community may unite, namely, in the healing of those diseased. It would seem advisable to set apart wards in general hospitals for this class of patients rather than that separate institutions should be established. These wards might be placed under the control of physicians who pay special attention to this department of medicine. Every barrier ought to be removed which would in any way prevent those diseased from applying for treatment, so that patients would find it to their advantage early to enter the hospital. They should be treated there with the same consideration as others, so as to remove that fear of control which deters many from applying for relief.

I am well aware that in many cities of this continent these or similar measures have been adopted, but there are still large communities in which little attention has been paid to the subject. How often do we hear it stated that public money should not be used in assisting this class. Such people forget that in allowing persons to remain diseased a still greater danger threatens the community at large. We are satisfied that in the democratic state of society which exists in all parts of North America more can be accomplished upon this than upon any other line yet proposed.

The careful examination of wet-nurses by competent physicians is an important point too often neglected. A bureau for the registration of nurses, such as exists in Moscow, would be found of service in our large cities. In that institution, according to a report made a few years ago, seventeen per cent. of the applicants for registration exhibited suspicious signs, while an additional four per cent. were undoubtedly affected by syphilis. The careful periodical examination of soldiers and sailors, and their immediate and thorough treatment when affected, are measures which ought to be easily enforced.

The spread of syphilis by vaccination and circumcision is a question which should be carefully looked into. Great differences of opinion exist as to what extent the youth of our country should be taught regarding the consequences which frequently follow venereal disease. Although much good may be done in this way the greatest care should be taken to state facts which can be easily comprehended by the listener. It is difficult to conceive of a subject which requires more good judgment, and it is to be deplored that instruction of the kind is often given by men in every way unfitted for the task.

The question of the spread of leprosy has for the last few months excited a good deal of attention in this country and in Europe. Addresses delivered by Dr. Morrow, in the New York Academy of Medicine, upon the history and spread of the disease in Mexico and in the Hawaiian Islands have excited the interest of professional men; while the death of Father Damien, in Molokai, has at the same time drawn popular attention to this subject.

It is very important that the thoughts of the people should be directed in a proper channel, when there is a disposition to deal with the question as one of a public character. Are there at present any grounds for alarm in consequence of the existence and spread of leprosy on this continent? Should measures be adopted for its eradication? and, if so, what course is likely to be successful?

The first question may be best answered by the statement of a few propositions about some of which the majority of scientific men are now agreed.

(1) That leprosy is contagious in the wider acceptation of that term is proved by the rapid spread in the the Hawaiian Islands, by its attacking persons not previously disposed to it after living for a time in a community of affected people, and by the discovery of a distinct bacillus which is intimately connected with the existence of the disease. Dr. Aring, in his report to the Hawaiian Government, made the following remarks with regard to contagion: "Accepting either theory, the direct or indirect transmission, we must look upon every individual leper, whether in the incipient or advanced stage of the disease, as a dangerous focus of the malady, he multiplying and nursing the germs in his own tissues." Dr. Aring further demonstrated the great vitality of the bacilli by finding them in cadavers which had been some months buried.

(2) That the disease can be conveyed from one to another by inoculation is a well-established fact. A number of cases of accidental inoculation have been reported, and the instance of the prisoner in whom the disease was produced in this way ought to set the matter at rest.

(3) That the germs may be introduced with food is a probability which has been much strengthened by Mr. Jonathan Hutchinson, in his paper recently contributed to the *British Medical Journal*.

(4) Dr. Mouritz, in his "Report on Leprosy as it existed in Molokai," dated February, 1886, ventures the opinion that the germs may be introduced by inhalation, and cites the case of Father Damien as an instance in illustration of this theory. The instances given certainly do not seem to prove the assertion, but we are not in a position to deny its truth. A great deal of weight should be given to the opinion of one who for two years has had the best opportunities for studying the disease.

(5) The hereditary transmission of leprosy was, until a few years ago, considered a settled question, and, in fact, the only way in which the spread of the disease could be accounted for. As a result of recent discoveries, the tendency of scientific opinion is in favor of the view that it is a predisposition to the malady which is hereditary, rather than the disease itself.

If the disease may be conveyed by any or all of these means, how can its slow progress on this continent be explained? There are records of cases which occurred in the early part of this century, and diseased persons have been allowed to come in from foreign lands, and still there has been no decided increase until of late years. Again, in leprous districts there are numerous instances of persons who have lived in the closest relationship with those affected, and that have themselves escaped. A marked case of this kind was reported by me in a paper on "Leprosy in New Brunswick," published in 1883.

The growth of the germs seems to depend largely upon the individual with whom they come in contact. In some races, for instance the Anglo-Saxon, as it now exists, there do not appear to be many susceptible individuals. This is strikingly shown in New Brunswick, where the disease exists almost exclusively among the French Canadians, or those connected by marriage with that race. Even then, however, there are some patients of purely Anglo-Saxon origin. In the Hawaiian Islands comparatively few of English or American descent have become affected. This immunity from the disease seems to depend upon our superior methods of living, rather than upon any racial peculiarities. It must, however, be remembered that in the most favored races there are some individuals who appear to be very susceptible, and who will contract the disease after comparatively slight exposure. Mr. Hutchinson has reported many such cases.

The conditions of the people on this continent have been such as in many ways to hinder the spread of disease. The population, as a rule, is not dense; and this is particulaly the case where leprosy is prevalent. In Minnesota, for instance, the dwellings cannot be very close together; and in Tracadie, although large families live in small houses, the whole district is more or less separated by miles of pine woods from other portions of the country.

Another explanation of the slow spread of leprosy exists in the fact that so far the disease has attacked other races than the Anglo-Saxon, and that there has been but little communication between affected persons and the latter race. In Louisiana and Canada the French race has principally suffered; in Minnesota, the Norwegian, and on the Pacific coast, the Chinese.

If, for instance, it were possible to send fifty or one hundred leprous persons of the Anglo-Saxon race into the poorer districts of one of our large cities, where they would mingle freely with the inhabitants, is it not reasonable to suppose that in a few years a number of new cases of leprosy would be developed?

In the same way, if one leprous person were so allowed to live, would it not be equally possible that three or four cases might arise, and the disease thus more slowly but quite as surely spread.

It is said that a wise statesman looks at least a hundred years ahead, and if in the year A. D. 2,000, there will be, as some statisticians say, 700,000,000 of people on the continent, or even half that number, and if the present process of centralization continues so that our large cities should become larger than any even in Europe, how impossible would it be to control this disease if it should become at all prevalent! It is probable that under such circumstances a large section of the community might become susceptible, and that leprosy might reach the dreaded proportion which at present exists in India.

In one respect the conditions are favorable for the extension of the disease, namely, that it exists in every quarter, — in the north, in New Brunswick; in the south, in Louisiana, Mexico and Trinidad; west, in California and British Columbia; while in Minnesota it is found in the very heart of the continent. Is it not possible that even now cases are coming into existence in these various localities? Indeed, only a few months ago three cases of leprosy were transferred from Cape Breton to Tracadie; and it is quite possible that diseased persons may still exist in that part of Nova Scotia.

It would thus appear that although there is no danger of a rapid spread of leprosy on this continent, there is a danger of its insidious propagation until it should reach proportions such as to make it very difficult to deal with. How hard it will be for the authorities of India to stamp out the disease, when, according to some authorities, there are nearly a quarter of million of lepers in that country!

According to statements made in a recent discussion on this subject in the New York Academy of Medicine, the number of cases on this continent has increased five-fold in the last ten years. Would it not be wiser for the various governments at once to adopt

means for the prevention of the disease rather than to wait until it has become more widely spread? These measures may be divided into two classes, the prevention of leprous persons from coming into the country, and the proper care of those who are already here. To carry out the first, it would be necessary that all suspicious emigrants should be examined by a physician thoroughly competent to diagnose the disease in its earlier stages, and if leprosy were present, they should at once be sent back to be dealt with as the authorities of their native country might determine. Doubtful cases, if allowed to remain, should be placed under surveillance for two or three years; at least experience has shown that.

The only successful method of controlling the disease in the country is the segregation of the lepers, and their complete separation from healthy persons. This is a measure very difficult to carry out, even when there are but few cases, as is shown by the history of such laws in New Brunswick. In that province it was found almost impossible to compel some diseased persons to enter the lazaretto. If such were the case when there were but a few sufferers, how much harder would it be to enforce the law were the number greatly increased! This difficulty is one of the strongest reasons why such laws should be enacted without delay.

As the disease exists in the three great sub-divisions of the continent, the United States, Canada and Mexico, it would appear necessary that an international understanding should be arrived at whereby an asylum might be established in each country, and that the law should make it compulsory for all persons in whom the disease exists in an active stage to be thus separated from the healthy portion of the community. Such asylums should be made in every way as far as possible desirable places of residence, and should be placed in charge of physicians who would make a careful study of the disease. More successful methods of treatment might thereby be discovered, thus greatly benefiting the unfortunate patients themselves.

Dr. White, in his address delivered at our first meeting at Niagara Falls, in 1874, in giving the various objects and aims of this then new organization, made the following remarks:

"In the division of our work will be included the consideration of questions which may be of national importance. Leprosy has been hovering about our borders for many years; has been introduced into the heart of the country by the importation of stock from a people prone to the disease; has been, according to a reliable report, prevailing to a limited degree within a restricted locality of our Southern States; all for many years, and yet we have seen no reason to fear that it should gain a serious hold upon us. We have regarded it as a disease so far removed from us by time and geographical position that it did not concern us especially; but the history of its progress in the Hawaiian Islands within the past few years, the growing intimacy of communication between them and us, and the immigration in enormous numbers to the Pacific Coast of a race with whom it is indigenous, make the establishment of a foot-hold of the disease upon our soil by no means improbable.

"The question of its possible contagion was lately revived by competent observers; and of its most effective management, as a part of State or international medicine, may demand before long our special attention."

In view of these remarks I feel that, in making the suggestions already offered, I am well within the scope of operations of this Association.

I have thus taken up a few points in the Prevention of Skin Diseases, in order that more attention may be directed to that subject. Some of the remarks may seem superfluous to those coming from districts where sanitary laws are fully carried out. It is, however, quite certain that in many States and cities little attention is paid to such regulations.

It has been the custom of former presidents to make suggestions pointing to the improvement of the Association. Some members are of opinion that the thorough and exhaustive discussion of one or two subjects each year might add to the interest of our meetings. Such subjects for discussion might be selected by the Council, who could also appoint a referee and co-referee to introduce them.

Another point which might be considered, is the advisability of making it a rule to hold our annual meetings in large centres of population. Some of the most interesting and useful features of our gatherings might be the exhibition of rare forms of skin diseases. This could only be developed by making such a rule as that just mentioned.

The past year is memorable by two events, the first International Congress held in Paris, and the first meeting of the Congress of German Dermatologists held in Prague. The formation of these Associations will no doubt greatly stimulate the study of dermatology, and we may expect abundant fruit in future years as the result of their labors.

I will conclude by declaring the Association open for business, according to the programme which you have all received.

PRESIDENT'S ADDRESS.
AMERICAN GYNECOLOGICAL SOCIETY.[1]

BY H. P. C. WILSON, M.D., BALTIMORE.

FELLOWS OF THE SOCIETY: — For the honor which you have conferred upon me in selecting me to preside over your deliberations, I tender you my hearty thanks. I realize that your partiality has overbalanced your judgment, that many now before me are more worthy of the honor, but not one more zealous for the good of this Society, not one more proud of the record it has made, not one more ambitious for its glorious future.

When I look down the line of pre-eminent men who have preceded me — some of whose names are as household words wherever the word "woman" is pronounced,— when I remember their achievements in this Society (as elsewhere), and realize that I stand here to take up the work which they have laid down, I should feel my utter helplessness, but for that generosity and support which I see beaming from every face before me.

As officers and privates, then, let us stand together in the future as in the past, a solid band battling for the truth in all that pertains to knowledge in obstetrics and gynecology. Let me congratulate you on meeting again under such favorable auspices in this charming city, always distinguished for its men of culture,

[1] Delivered at the Fourteenth Annual Meeting, Boston, September 18, 1889.

its lights in science, its overflowing hospitality, — "a feast of reason and a flow of soul," are vouchsafed to us. Here we shall study obstetrics and gynecology pure and unadulterated (which is the sole purpose of this Society), free from the distractions of all other ologies, free from the interruptions of large assemblies with so many diversified interests. Here, too, we shall again cultivate those social qualities which have been such a charm at our annual meetings, and which have drawn us so closely together.

The social feature of this Society is far more than mere eating and drinking; it brings the fellows together in such close intimacy that the views of one are readily exchanged for the views of another; minute points in science and practice are explained by man to man; obscure points in papers and debates are made clear; little things in operations and therapeutics (so essential) are elucidated, as cannot be done in the set essays and impromptu debates of the stated meetings. In mercantile language, our social gatherings are Gynecology on Change; and we would hold on to them as a powerful lever in elevating this Society.

On the 3d of June, 1876, in the Hall of the New York Academy of Medicine, nineteen gentlemen were assembled to found the American Gynecological Society. Twenty others, who were prevented from being present, sent in their approbation and hearty co-operation in the work undertaken; and thus thirty-nine names constituted the foundation fellows of this Society. Of these eight are dead: E. R. Peaslee, J. Marion Sims, W. L. Atlee, Albert H. Smith, J. P. White, J. D. Trask, Charles Buckingham, Ellerslie Wallace. "When shall we look upon their like again?" "They rest from their labors, but their works do follow them." Five have resigned on account of age, ill-health or other unavoidable causes. They have helped to bear the heat and burden of the day, and rest on their honors. As the shades of evening draw around them, our blessings rest upon them. Thus, of the thirty-nine foundation fellows, thirteen have passed from active membership. One-third of our original number are gone by death and resignation.

Of those who have joined us by election, we have lost eight, — five by resignation and three by death. The latter are, Drs. John Scott, James B. Hunter and Ellwood Wilson, — making twenty-one fellows in all lost to active fellowship in this Society since its foundation.

To Dr. James R. Chadwick, of Boston, is due the conception of this Society. To Dr. Fordyce Barker, more than to any other single fellow, is due its rapid growth to the stature of a strong and full-grown man. The recognition of his pre-eminent abilities, and of his labors in its behalf, has been manifested by his having been three times called unanimously to preside over its meetings, an honor which has never been accorded to any other fellow; and, while naming these, I would not detract one iota from the vigorous work by other fellows who have done so much to make the American Gynecological Society what it is to-day. Their labors are before you in our published transactions, and crown them with honor.

On the 13th of September, 1876, more than thirteen years ago, we held our first annual meeting in the hall of the New York Academy of Medicine. Twenty-eight fellows were present, and a number of distinguished foreign guests. It was my privilege to be there, and it has been with great pleasure and profit that I have attended every annual meeting since. I have always been present to answer to my name when the roll was called, and have never left till after final adjournment. I have watched with great interest and pride the history of this Society. To it can be traced many of my greatest achievements in life, and through it have been made many of my best and dearest friends. It is no wonder, then, that I should be proud of the appreciation in which it is held at home, and the fame that follows it abroad.

Whenever I have been in foreign lands, it has frequently been a passport to me in medical circles to be known as a member of the American Gynecological Society. I have repeatedly been told by medical men in Europe of the admiration they had for this Society, and the pleasure it would give them to be of its membership; and it has gained for me access to persons and places from which I should otherwise have been excluded.

It is of the first importance to me then, as to every fellow, that the reputation of this Society should be maintained, — yea, lifted far above its present elevated position. We must advance, and not rest on our past achievements.

I have already told you how many of the founders of this Society are gone; how many more are travelling down the hill of life burdened with the weight of years and loaded with innumerable cares; and how many more, in the prime of life, are overwhelmed by the daily duties of practical gynecology, from early morn to lingering eve, with nothing left of time or strength for scientific investigations. These are the men, who, under great difficulties as pioneers, have done so much to bring gynecology to what it is to-day. Nothing daunted by the shafts of ridicule, the detractions of jealousy, the threats of prosecution, Sims and his followers have pressed onward till this branch of medicine is now established on everlasting foundations.

In the natural course of things these early workers must soon rest from their labors. Their scalpels and speculums must pass into other hands; but it is with great pleasure and satisfaction that, in looking over this assemblage, I see so many men of youth, strength, diligence, brilliancy of mind and nobleness of purpose, to whom the interests of this Society can be entrusted, with the assurance that its position will be placed higher and higher in the temple of fame. Older men must step one side; younger men must take up the burden.

For the future of this Society nothing has given me more anxiety than the selection of new fellows. We want, as members, the best men in our land, men of brains, laborious men, gentlemen; men, who with cultivated minds, by patient research, can verify or disprove many of our crude pathological ideas. We want more scientific investigation into the pathology of the disease we are called on to treat. Sound pathology always insures better therapeutics. This kind of work cannot be demanded of the older members, who are constantly overwhelmed with the cares of daily practice, and whose minds are preoccupied with the questions of saving life and alleviating suffering.

It is to the younger men of this Society that we must especially look for contributions of original research, which in time, I trust, will make its transac-

tions the storehouse of all that is sound in doctrine and best in practice.

They are not yet overwhelmed with patients; and while they have the time, the strength, the fire of youth, which stimulates to exploration, we would call on them to work for gynecology, as they will not be able to do in later years. Then gynecology will work for them.

I would increase the membership of this Society, not because "in a multitude of counsellors there is wisdom" (this is not always true), but because from our widely extended country many fellows are frequently unable to attend the annual meetings, and we are sometimes reduced to a small working force. Again, with a larger membership, we would have greater diversity of talent from which to bring forth things new and old.

I would abolish the third article of the constitution, which relates to the election of fellows. I would enlarge our number from time to time by invitations to join, and cut off all applications for membership. It was by invitations that this Society was formed. It should be by invitations that it is continued and enlarged. In this way we would get the best men in our country, many of whom are now deterred by the gauntlet they have to run from applying for membership. In this way also we should escape some of the unpleasant things which confront us at each business meeting.

I would restrain this Society from all entangling alliances with other societies. The distractions of such large assemblies are not promotive of the best work in any specialty. If we would make it the great authority on all gynecological subjects, if we would make it the first in wisdom as the first in age, we must abstain from too much allegiance to other societies, and let our full strength be concentrated here. Whatever time and labor are expended on them will be subtracted from this, and by so much will its vigor and strength be diminished.

I would hold with unyielding tenacity to the social feature of this Society. Nothing should be allowed to interfere with it. The cultivation of the heart is hardly second to the cultivation of the head. Cold comfort is a damper to the soul. Nothing so much as social gatherings has tended to bind us so firmly together — a united band of brethren.

LAPAROTOMY DURING MENSTRUATION.

But, gentlemen, before closing this address, which you have required me to deliver, and which is more trying to me than many laparotomies, I must present you with one question: Shall we perform laparotomy immediately preceding or during menstruation?

This is a question which frequently embarrassed me in my earlier professional experience. Books were searched and authorities consulted for its elucidation; but I found nothing to enlighten me on the subject. The medical friends with whom I consulted advised against such a procedure. In addition to this came the paper of Dr. Horatio R. Storer, read at the first meeting of this Society, in 1876, in which he concluded "that for pelvic operations, all things being equal, it is better to select the week immediately following the cessation of the catamenia," for all such operations.

Operations per vaginam may require the selection of the uterine ebb, where such choice can be made, as the dressings and attention necessary afterward may be embarrassed by menstruation; but for laparotomies involving the pelvic organs, my experience teaches me to select the uterine flood, rather than the uterine ebb. During the uterine flood, the circulation and innervation are in a state of tonic excitement. During the uterine ebb they are in a state of relaxation and depression; and patients thus are more liable to passive hæmorrhages, the absorption of septic poison, the deadly influence of shock, than when the system is under the stimulus of the uterine flood.

It may be said that inflammatory troubles are more apt to be set up during the uterine flood. I would ask the Fellows how many of their laparotomies have been lost by inflammation other than septic. I cannot recall one in my own experience. Shock, hæmorrhage, and blood-poison have been the causes of death in all cases, and blood-poison oftener than all other causes together.

On June 19, 1871, more than eighteen years ago, I performed ovariotomy on Mrs. C. C. W. The operation had been fixed for that day; all arrangements had been made. The weather was extremely hot, and the patient was alarmingly feeble. All efforts to build up her strength were futile. She was rapidly losing strength, and I realized that she could not survive much longer. When I reached the house, where a number of physicians were assembled, I found that Mrs. W. was menstruating very freely, about six days before her time. I was in great perplexity what to do. With the patient's great feebleness and the debilitating effects of the intense heat of summer in a large city, I did not think she could much longer survive. My preconceived opinion was that no operation on any of the pelvic organs should be done during menstruation. There was no authority to which I could turn to extricate me from my dilemma. My professional brethren present did not venture an opinion. I finally came to the unassisted conclusion that it was more dangerous to my patient for me to retreat than to advance. I removed the tumor. The woman made a good recovery. Her menses were very free for several days after the operation. This was my second case of ovariotomy — both successful.

In December, 1880, I removed both ovaries from Miss A. E. by abdominal section. This was the first operation of the kind by this method in the State of Maryland. The operation was done to bring on the menopause, for a bleeding myoma in the uterine walls. She was within four days of menstruation. It came on the night of the day of the operation, and was very profuse. She is now living, in perfect health, and married, taking care of her paralyzed husband and a large family of children by his former wife.

I might go on to report many cases on whom I had performed laparotomy very near or during menstruation, but I will not detain you. Within the past year I have done a number of such, and every one recovered. I have never lost a case of laparotomy done immediately before or during a menstruation, and I am thus forced to make the uterine flood the time of selection for such operations, rather than the uterine ebb.

But, gentlemen, there is a limit to all things, even to your patience, which has been great. I thank you for your kindness. You will thank me for — well, I will not say what. A few words more and I am done.

Since our last annual meeting Death has dealt us a

terrible blow in cutting down two of our most esteemed and honored fellows, Drs. James B. Hunter and Ellwood Wilson. In no single year before has he been so merciless to us — two, for one in all previous years. The strength of this Society is made up of just such material. They were corner-stones in this superstructure. As one stone crumbles, another stronger one must replace it. To other hands I leave the preparation of memorials worthy of their characters, while we sorrow over our loss.

"In the midst of life we are in death." Who shall be the next to fall? God grant that we may so live as to be prepared to die.

PRESIDENT'S ADDRESS. AMERICAN ORTHOPEDIC ASSOCIATION.[1]

BY E. H. BRADFORD, M.D.

Before beginning the regular exercises of our Third Annual Meeting, it will be well for a few moments to bring to mind, the facts which have led to the organization of this Association.

Our Association is a pioneer association in the department of orthopedic surgery. This brings with it both honor and responsibility; for the department of surgery we are interested in will be promoted or injured according as our work is equal to or falls short of the opportunity, and we must clearly bear in mind that the progress of orthopedic surgery has not been that of uninterrupted advance.

The history of this branch of surgery has been often told, the first attempts in the correction of deformities is perhaps as old as surgery. The existence of this special branch may be said to date from the work of Andry, who, in the last century gave it a name; and it is due chiefly to a remarkable group of French surgeons, — Delpech, Bouvier, Bonnet, Malgaigne, Guerin, Pravaz, — that the specialty may be said to owe its breath of life. The German surgeons Stromeyer, Heine, Dieffenback, Langenbeck fully equalled the French in their efforts, and too much cannot be said in praise of the work of the English surgeons. Percival Pott's name is stamped indelibly on the records of our specialty; the work of Sheldrake is a tradition for us. It is, however, to Little and his school, that we Americans are more indebted than to any other foreign influence in moulding our current practice.

Even at the present time when orthopedic surgery is so well established as is now the case in America, it is easy to note European influences, — especially that of German surgery; Boeckel and Ollier, of France; Macewen, of Glasgow; and Thomas, of Liverpool.

But though great progress was made in orthopedic surgery, it is not to be overlooked that it fell from the high estate it held in general surgical interest fifty years ago, until it became an almost despised and rejected branch. The orthopedic surgeon was regarded as a man of mere straps and buckles, or the custodian of that surgical chamber of horrors, the orthopedic institute. The reason of this decline of interest is not far to seek, if we recall the fact that fifty years ago the attention of the surgical world was turned to the remarkable feats of the great surgeons who taught us precision, skill and boldness in the triumphs of the amphitheatre, and that the ambition of all men of energy prompted them to emulate those monarchs of the operating-table. The famous line in the Iliad,

Ἰητρὸς γὰρ ἀνὴρ πολλῶν ἀντάξιος ἄλλων,

was interpreted to mean the surgeon whose feats meant so much for humanity.

Following this period came the introduction of anæsthetics, which enormously enlarged the field of possible operations; and subsequently came the introduction and perfection of the antiseptic system which has enabled the surgeon to perform in his operations veritable marvels.

It is not strange that in the active current of progress the less brilliant branch of orthopedic surgery, where successes can rarely be won in the amphitheatre, and where the element of patient, persistent work is an important fact, should have been for the while passed aside by the energetic and ambitious.

The history of American orthopedic surgery shows, in a degree, the same tendency in development that existed in Europe, the same interest at one period and the same decline. In the last generation, however, when American arts and sciences had begun to free themselves from the provincialism of mere imitation of European models, the natural spirit of mechanical ingenuity became manifest in this branch of surgery. This has, perhaps, in some cases led to mechanical extravagance; but it will be universally admitted that a marked advance has been won, and that the tendency is in the right direction.

The history of orthopedic surgery in America can never be thoroughly written, as the earlier facilities for presenting cases and recording methods were necessarily imperfect in a new country. The earlier American bibliography, prior to 1860, which, through the kindness of Dr. Billings, has been copied for me from the catalogue of the Army Medical Library, shows not only much that is of interest, but indicates by what is implied as much as by what is published, that much excellent work was done which escapes the annalist.

The first triumph in orthopedic surgery in America is the classical operation by Rhea Barton (*North American Medical and Surgical Journal*, 1827, p. 279), the founder of osteotomy for correction of deformity, as McDowell is the founder of ovariotomy.

Physick's Fixation Hip Splint, described in 1831; Chase's paper on the "Treatment of Club Foot without Tenotomy" (*American Journal of Medical Sciences*), 1841; Mütter's work on "Club Foot," in 1845, — all indicate the intelligent interest taken in the subject. Excision of the hip was first performed in this country by Dr. Wilcox, of Eastern Pennsylvania, as early as 1849.

The stimulus of Stromeyer's achievements was quickly felt in America; and tenotomies were done by Rogers (1834), Dickson (1835) and Detmold (1837). To the latter belongs the credit of the first published tenotomy, the tenotomies of the two former surgeons not having been recorded. Detmold also acted *ex cathedra*, as it were, for he was fresh from the teachings of Stromeyer. The interest taken by general surgeons of the time in orthopedic surgery is indicated by the remarks of Valentine Mott, as quoted by Mütter, of Philadelphia, and by the well-known work on "Orthopedic Surgery," by Dr. Henry J. Bigelow, published in 1845, and which to-day is a model of excellence, and one of the best of publications to

[1] Delivered at the Third Annual Meeting, Boston, September 17, 1889.

illustrate the French school of orthopedic surgery, the dominant school of the time.

An operation by Dr. Sargent, of Worcester, the section of the psoas and iliacus muscle, reported before the Worcester Medical Society in 1841, was a triumph of boldness, and should not be passed unnoticed.[2] The following account is copied from the records of the Worcester District Medical Society, meeting of October 6, 1841:

"Dr. Sargent said he should relate some cases of contraction of the tendons.

"CASE I was one of contraction of tendons of lower extremities in a child, with antero-posterior curvature of the spine, adduction of both thighs so that the knees were drawn firmly together, also extension of feet from contraction of the gastrocnemii muscles. First divided the adductor longus of the right thigh, which immediately relieved its position, and abduction became perfectly easy, and in a few days the limb assumes natural position when patient lies on his back. Three days after this the same operation was performed on the left thigh with similar results. Seven days after last operation cut tendo Achillis of each heel which 'let both down at once as low as the toes'; feet assumed natural position; was able to stand on his feet in a month after operation on heels. At the present time (about nine months after operation) there is still want of control over motions of hip-joint. Walking very much improved; can go very well with only one cane; before operation could only waddle along sidewise upon his toes by leaning upon two canes.
